THE POWER-SAVING MANIN-PEYRE CONJECTURE
FOR A SENARY CUBIC

SANDRO BETTIN AND KEVIN DESTAGNOL

Abstract. Using recent work of the first author [3], we prove a strong version of the Manin-Peyre’s conjectures with a full asymptotic and a power-saving error term for the two varieties respectively in \(\mathbb{P}^2 \times \mathbb{P}^2\) with bihomogeneous coordinates \([x_1 : x_2 : x_3], [y_1 : y_2, y_3]\) and in \(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1\) with multihomogeneous coordinates \([x_1 : y_1], [x_2 : y_2], [x_3 : y_3]\) defined by the same equation \(x_1 y_2 y_3 + x_2 y_1 y_3 + x_3 y_1 y_2 = 0\). We thus improve on recent work of Blomer, Brüdern and Salberger [8] and provide a different proof based on a descent on the universal torsor of the conjectures in the case of a del Pezzo surface of degree 6 with singularity type \(A_1\) and three lines (the other existing proof relying on harmonic analysis [17]). Together with [7] or with recent work of the second author [21], this settles the study of the Manin-Peyre’s conjectures for this equation.

1. Introduction

In the late 80s, Manin and his collaborators [22] proposed a precise conjecture predicting, for smooth Fano varieties, the behaviour of the number of rational points of bounded height (with respect to an anticanonical height function) in terms of geometric invariants of the variety. The conjecture was later generalised by Peyre [26] to “almost Fano” varieties in the sense of [26 Définition 3.1].

1991 Mathematics Subject Classification. 11D45, 11N37, 11M41.
Key words and phrases. Manin-Peyre’s conjectures, divisor function.
Conjecture 1.1 (Manin, 1989). Let $V$ be an “almost Fano” variety in the sense of [25 Définition 3.1] with $V(Q) \neq \emptyset$ and let $H$ be an anticanonical height function on $V(Q)$. Then there exists a Zariski open subset $U$ of $V$ and a constant $c_{H,V}$ such that, for $B \geq 1$,
\[ N_{U,H}(B) := \#\{ x \in U(Q) \mid H(x) \leq B \} = c_{H,V}B \log(B)^{\rho-1}(1 + o(1)), \]
where $\rho = \text{rank}(\text{Pic}(V))$.

Peyre [26], and then Batyrev and Tschinke [2], and Salberger [28] in a more general setting, also proposed a conjectural expression for the constant $c_{H,V}$ in terms of geometric invariants of the variety. We do not record this conjecture here in any more details and refer the interested reader to [27] for example. There are a number of refinements of the Manin-Peyre conjectures and we will focus throughout this paper on the following one [15].

Conjecture 1.2 (Refinement of the Manin-Peyre’s conjectures). Let $V$ be an “almost Fano” variety in the sense of [25 Définition 3.1] with $V(Q) \neq \emptyset$ and let $H$ be an anticanonical height function on $V(Q)$. Then there exists a Zariski open subset $U$ of $V$, a polynomial $P_{U,H}$ of degree $\rho$ and $\delta \in]0, 1[\ such that, for $B \geq 1$\n\[ N_{U,H}(B) = B P_{U,H}(\log B) + O(B^{1-\delta}), \]
where $\rho = \text{rank}(\text{Pic}(V))$ and the leading coefficient of $P_{U,H}$ agrees with Peyre’s prediction.

There has been very little investigations on the lower order coefficients and this seems to be a difficult question but the examples we study in this paper might be an interesting testing ground.

These two conjectures have been the center of numerous investigations in the past few years using techniques from harmonic analysis in the case of equivariant compactifications of some algebraic groups (see for example [11, 130]) or from analytic number theory and more specifically the circle method in the case where the number of variables is large enough with respect to the degree (see for example [5, 10]). In the remaining cases, the only available method relies on a combination of analytic number theory or geometry of number and on a descent on some quasi-versal torsors in the sense of [18]. Most of these investigations (especially in cases relying on a descent) are concerned with surfaces (see for example works of Browning, La Bretèche, Derenthal and Peyre [11, 12, 14]), whereas very little is known in higher dimensions. In particular there are only very few examples of varieties in higher dimension for which Conjecture 1.2 or even Conjecture 1.1 is known to hold using such a descent argument (see [9, 29, 7, 21]). The goal of this paper is to give another such example.

In this paper we shall consider the solutions to the equation
(1.1)
\[ x_1y_2y_3 \cdots y_n + x_2y_1y_3 \cdots y_n + \cdots + x_ny_1y_2 \cdots y_{n-1} = 0. \]
Notice that, upon excluding the points for which $y_1 \cdots y_n = 0$, one can also rewrite the above equation as a linear equation between fractions
\[ \frac{x_1}{y_1} + \cdots + \frac{x_n}{y_n} = 0. \]
We shall focus on the case $n = 3$ in the present paper. The cases $n \geq 4$ will be the subject of future work.

One can view equation (1.1) in three natural ways. First, one can consider the singular projective hypersurface of $\mathbb{P}^{2n-1}$ with homogeneous coordinates $[x_1 : \cdots : x_n : y_1 : \cdots : y_n]$ defined by (1.1). This was done in 2014 by Blomer, Brüdern and Salberger who in [2] proved Conjecture 1.2 for $n = 3$ using a combination of lattice point counting and analytic counting by multiple Mellin integrals. This setting was also studied by the second author [21] who, by elementary counting methods, proved Conjecture 1.1 when $n \geq 2$ for the following anticanonical height function
\[ H([x_1 : \cdots : x_n : y_1 : \cdots : y_n]) = \max_{1 \leq i \leq n} \max \{|x_i|, |y_i|\}^n. \]
It is worth noticing that in this case, the varieties under consideration are equivariant compactifications of the algebraic groups $\mathbb{G}^{n-1}_a \times \mathbb{G}^{n-1}_m$. Harmonic analysis techniques might also be able to handle this.
case and to prove Conjecture \[1.2\] for every \( n \geq 4 \). To our knowledge this hasn’t been done so far, but it would be interesting to compare this approach with a generalization of the methods of [7] or of the present paper.

One can also think of (1.1) as defining the singular biprojective variety \( \tilde{W}_3 \) of \((\mathbb{P}^{n-1})^2\) with bihomogeneous coordinates \([x_1 : \cdots : x_n], [y_1 : \cdots : y_n]\) defined by the equation (1.1). An anticanonical height function is then given by

\[
\tilde{H}([x_1 : \cdots : x_n], [y_1 : \cdots : y_n]) = \max_{1 \leq i \leq n} |x_i|^{n-1} \max_{1 \leq i \leq n} |y_i|.
\]

In this case, the varieties under consideration are not equivariant compactifications, the rank of the Picard group of \( \tilde{W}_n \) is \( 2^n - n \) and the subset where \( x_1 \cdots x_n y_1 \cdots y_n = 0 \) is an accumulating subset. In recent work [8], Blomer, Brüdern and Salberger showed that Conjecture 1.1 holds for \( \tilde{W}_3 \). Using recent results of the first author [4], we are able to refine the aforementioned result [8] proving the stronger Conjecture \[1.2\] for \( \tilde{W}_3 \).

**Theorem 1.** Let \( \tilde{U} \) be the Zariski open subset of \( \tilde{W}_3 \) given by the condition \( x_1 x_2 x_3 y_1 y_2 y_3 \neq 0 \). There exist \( \xi_1 > 0 \) and a polynomial \( P_1 \) of degree 4 such that

\[
N_{\tilde{W}_3, \tilde{H}}(B) := \# \left\{ ([x_1 : x_2 : x_3], [y_1 : y_2 : y_3]) \in \tilde{U}(\mathbb{Q}) \mid \tilde{H}(x, y) \leq B \right\} = BP_1(\log B) + O(B^{1-\xi_1}).
\]

The leading coefficient of \( P_1 \) is equal to \( \frac{\xi_1 \mathcal{I}}{144} \), where

\[
\mathcal{S}_1 := \prod_p \left( 1 - \frac{1}{p} \right)^5 \left( 1 + \frac{5}{p} + \frac{5}{p^2} + \frac{1}{p^3} \right),
\]

\[
\mathcal{I} := \int_{[0,1]^2} \chi_{\{0,1/2\}}(x_1, y_1) dx_1 dy_1 = \pi^2 + 24 \log 2 - 3
\]

and \( \chi_X \) denotes the characteristic function of a set \( X \).

The work of [8] shows that \( \frac{\xi_1 \mathcal{I}}{144} \) coincides with Peyre’s prediction for this variety and so Theorem 1 gives Conjecture 1.2 for \( \tilde{W}_3 \).

Finally, a third interpretation of (1.1) is as the singular subvariety \( \hat{W}_n \) of \((\mathbb{P}^1)^n\) with multihomogeneous coordinates \([x_1 : y_1], \ldots, [x_n : y_n]\). The only record of study of an analogous equation is from La Bretèche [10] but with a non anticanonical height function. An anticanonical height is given in this setting by

\[
\tilde{H}([x_1 : y_1], \ldots, [x_n : y_n]) = \prod_{i=1}^n \max\{|x_i|, |y_i|\}.
\]

We prove the two following theorems which, combined, give that Conjecture 1.2 holds for \( \tilde{W}_3 \).

**Theorem 2.** Let \( \tilde{U} \) be the Zariski open of \( \tilde{W}_3 \) defined by the condition \( y_1 y_2 y_3 \neq 0 \). Then there exist \( \xi_2 > 0 \) and a polynomial \( P_2 \) of degree 3 such that

\[
N_{\tilde{W}_3, \tilde{H}}(B) := \# \left\{ ([x_1 : y_1], [x_2 : y_2], [x_3 : y_3]) \in \tilde{U}(\mathbb{Q}) \mid \tilde{H}(x, y) \leq B \right\} = BP_2(\log B) + O(B^{1-\xi_2}).
\]

The leading coefficient of \( P_2 \) is equal to \( \frac{\xi_2 \mathcal{I}}{144} \), where \( \mathcal{I} \) is as in Theorem 1 and

\[
\mathcal{S}_2 := \prod_p \left( 1 - \frac{1}{p} \right)^4 \left( 1 + \frac{4}{p} + \frac{1}{p^2} \right).
\]

**Theorem 3.** The variety \( \tilde{W}_3 \) is isomorphic to a del Pezzo surface of degree 6 with singularity type \( A_1 \) and 3 lines over \( \mathbb{Q} \) and the leading constant of the polynomial \( P_2 \) in Theorem 2 agrees with Peyre’s prediction.
We remark that by Theorem 3 and [25] one has that $\tilde{W}_3$ is an equivariant compactification of $G_a^2$. In particular Theorem 2 follows from the more general work of Chambert-Loir and Tschinkel [17].

The purpose of giving a new independent proof of Theorem 2 is double. First, the method presented here uses a descent on the versal torsor and thus it is different from the method in [17] which relies on harmonic analysis techniques and the study of the height zeta function. To our knowledge this is the first time that a full asymptotic with a power-saving error term is obtained on this del Pezzo surface by means of a descent on the versal torsor. The best result using such a method can be found in [15, Chapter 5] where Browning obtains a statement somewhere in between Conjectures 1.1 and 1.2.

Secondly, following the same approach for proving Theorem 1 and 2 allows one to appreciate the difference in the structure of the main terms in these two cases, showing how the extraction of the main term in the first case becomes substantially harder as well as allowing the use the proof of Theorem 2 as a guide for that of Theorem 1.

**Remark.** We prove Theorem 2 for any $\xi_2 < \frac{0.00228169}{\ldots}$ One can easily give an explicit power saving also in the case of Theorem 1 as well as improving the allowed range for $\xi_2$, but in order to simplify the presentation we choose not to do so, since in any case the values obtained could be greatly improved by tailoring the methods of [1] to these specific problems.

The proofs of Theorem 1 and 2 roughly proceed as follows. We use the same unique factorization as in recent work of the second author [21] to parametrize the counting problem combined with recent work of the first author [4]. More precisely, by means of a descent on the versal torsor we can transform the problem of counting solutions to (1.1) to that of counting solutions to $a_1x_1z_1 + a_2x_2z_2 + a_3x_3z_3 = 0$ with some coprimality conditions, with certain restraints on the sizes of $x_1, z_1$ (depending on the height we had originally chosen), and with $a_1, a_2, a_3$ that can be thought of being very small. By [4] (see also [3]) we have the meromorphic continuation for the “parabolic Eisenstein series”

$$\sum_{m_1, m_2, m_3 \geq 0 \atop a_1 m_1 + a_2 m_2 + a_3 m_3 = 0} \frac{\tau_{\alpha_1, \beta_1}(m_1) \tau_{\alpha_2, \beta_2}(m_2) \tau_{\alpha_3, \beta_3}(m_3)}{(m_1 m_2 m_3)^s}, \quad \Re(s) > \frac{2}{3} - \min(\Re(\alpha_i), \Re(\beta_i)) \quad \forall i = 1, 2, 3$$

where $\tau_{\alpha_1, \beta_1}(m) = \sum_{d_1d_2 = m} d_1^{-\alpha_1} d_2^{-\beta_1}$ for $(\alpha_1, \alpha_2, \alpha_3), (\beta_1, \beta_2, \beta_3) \in \mathbb{C}^3$. Using this we obtain that the counting problem in both cases is given by a certain multiple complex integral of the products of $\Gamma$ and $\zeta$ functions, up to a power saving error term. The main part of the paper is then devoted to the use of complex analytic methods to extract the main terms from such integrals. This process is reminiscent of the work [19] of La Bretêche, where he showed how to deduce asymptotic formulas for generic arithmetic averages from the analytic properties of their associated Dirichlet series. However, his work is not directly applicable to our case. Indeed, in his setting all variables are summed in boxes, whereas in our case the main action happens at complicated hyperbolic spikes. Of course, one could use La Bretêche’s work in combination with some suitable version of the hyperbola method, but in fact this would not simplify substantially the problem and would still eventually require arithmetic and complex-analytic computations essentially equivalent to ours. For this reason, we prefered to approach the relevant sums in a more direct way.

The paper is structured as follows. First, in Section 2 we reparametrize the solutions to (1.1) using a descent on the versal torsor. In Section 3 we prove Theorem 3. In Section 4 we state the main Lemma on the parabolic Eisenstein series and a smoothing lemma useful to avoid problems of sharp cut-offs. Then, in Section 5, 6, and 7 we prove Theorems 2 and 1 in three steps of increasing difficulties: first Theorem 2 without the aforementioned coprimality conditions, then we include these conditions and finally we prove Theorem 1.

**Notations**

We use the vector notation $v = (v_1, \ldots, v_k)$ where the dimension is clear from the context. Also, given a vector $v \in \mathbb{C}^k$ and $c \in \mathbb{C}$ with $v + c$ we mean $(v_1 + c, \ldots, v_k + c)$. With $\int$ we indicate the integration with respect to several variables, whose number is clear from the context. For $c \in \mathbb{R}$, with
\[ \int_{c} \text{we indicate that the integral is taken along the vertical line from } c-i\infty \text{ to } c+i\infty. \] Also, we indicate with \( c \), the line of integration corresponding to the variable \( z \). Given, \( a_1, \ldots, a_k \in \mathbb{Z} \) we indicate the GCD and the HCF of \( a_1, \ldots, a_k \) by \((a_1, \ldots, a_k)\) and \([a_1, \ldots, a_k]\) respectively.

We indicate the real and imaginary part of a complex number \( s \in \mathbb{C} \) by \( \sigma \) and \( t \) respectively, so that \( s = \sigma + it \). Also, \( \varepsilon \) will denote an arbitrary small and positive real number, which is assumed to be sufficiently small and upon which all bounds are allowed to depend. Finally, in Section \( 7 \) we denote by \( C_1, C_2, C_3, \ldots \) a sequence of fixed positive real numbers.

2. The descent on the versal torsor

For \( n \geq 2 \), we let \( N = 2^n - 1 \). For every \( h \in \{1, \ldots, N\} \), we denote its binary expansion by

\[ h = \sum_{1 \leq j \leq n} \epsilon_j(h)2^{j-1}, \]

with \( \epsilon_j(h) \in \{0, 1\} \). We will let \( s(h) = \sum_{j \geq 1} \epsilon_j(h) \) be the sum of the bits of \( h \). We will say that an integer \( h \) is dominated by \( \ell \) if for every \( j \in \mathbb{N} \), we have \( \epsilon_j(h) \leq \epsilon_j(\ell) \). We will use the notation \( h \preceq \ell \) to indicate that \( h \) is dominated by \( \ell \). We will say that an \( N \)-tuple \((z_1, \ldots, z_N)\) is reduced if \( \gcd(z_h, z_\ell) = 1 \) when \( h \not\preceq \ell \) and \( \ell \not\preceq h \).

We give the following lemma which gives a unique factorization for the variables \( y_j \) inspired by \[24\] [13] and [10] and which will be very useful to parametrize rational solutions of \((1.1)\).

**Lemma 1 ([13]).** There is a one-to-one correspondence between the \( n \)-tuples of non negative integers \((y_i)_{1 \leq i \leq n}\) and the reduced \( N \)-tuples \((z_h)_{1 \leq h \leq N}\) of non negative integers such that

\[ \forall j \in [1, n], \quad y_j = \prod_{1 \leq h \leq N} z_{j}^{\epsilon_j(h)} \quad \text{and} \quad [y_1, \ldots, y_n] = \prod_{1 \leq h \leq N} z_h. \]

2.1. The case of \( \widehat{W}_n \). Let \( n \geq 2 \). We want to estimate, for \( B \geq 1 \), the quantity

\[ N_{\widehat{W}_n, \widehat{H}}(B) := \# \left\{ ([x_1 : y_1], \ldots, [x_n : y_n]) \in \widehat{U}(\mathbb{Q}) \mid \widehat{H}(x, y) \leq B \right\}. \]

Clearly, we have

\[ N_{\widehat{W}_n, \widehat{H}}(B) = \# \left\{ (x, y) \in \mathbb{Z}^n \times \mathbb{Z}_{\geq 0}^n : \begin{array}{l} \widehat{H}(x, y) \leq B \\ (x, y) \text{ satisfies } (1.1), \gcd(x_i, y_i) = 1 \end{array} \right\}. \]

Using Lemma 1, the equation \((1.1)\) can be rewritten as

\[ \sum_{j=1}^{n} d_j x_j = 0 \quad \text{with} \quad d_i = \prod_{1 \leq h \leq N} z_h^{1-\epsilon_i(h)}, \quad \forall i \in [1, n]. \]

We then obtain the divisibility relation \( z_{2j-1} \mid x_j \) for every \( j \in \{1, \ldots, n\} \). Since we have the conditions \( \gcd(x_j, y_j) = 1 \) and \( z_{2j-1} \mid y_j \), we can deduce that for every \( j \in \{1, \ldots, n\} \), \( z_{2j-1} = 1 \). Finally, we have

\[ N_{\widehat{W}_n, \widehat{H}}(B) = \# \left\{ (x, z) \in \mathbb{Z}^n \times \mathbb{Z}_{\geq 0}^{N-n} : \begin{array}{l} \prod_{i=1}^{n} \max \left\{ [x_i], \prod_{1 \leq h \leq N} |z_h|^{\epsilon_i(h)} \right\} \leq B \\ \text{\( (z_h)_{1 \leq h \leq N} \) reduced,} \quad \sum_{i=1}^{n} x_i d_i = 0 \end{array} \right\}. \]
In the case \( n = 3 \), renaming for simplicity \( z_6 \) by \( z_1 \), \( z_5 \) by \( z_2 \) and \( z_7 \) by \( z_4 \), one gets the following expression for \( N_{\tilde{W}_3, \tilde{H}}(B) \)

\[
N_{\tilde{W}_3, \tilde{H}}(B) = \left\{ (x, z) \in \mathbb{Z}^3 \times \mathbb{Z}^4_{>0} : \begin{array}{l}
\gcd(x_1, z_2 z_3 z_4) = \gcd(x_2, z_1 z_3 z_4) = \gcd(x_3, z_1 z_2 z_4) = 1 \\
\gcd(z_1, z_2) = \gcd(z_1, z_3) = \gcd(z_2, z_3) = 1 \\
\max\{|x_1|, z_2 z_3 z_4\} \times \max\{|x_2|, z_1 z_3 z_4\} \times \max\{|x_3|, z_1 z_2 z_4\} \leq B \\
x_1 z_1 + x_2 z_2 + x_3 z_3 = 0
\end{array} \right\}.
\]

As explained in Section \( 3 \), the open subvariety of \( \mathbb{A}^7 \) given by the equation \( x_1 z_1 + x_2 z_2 + x_3 z_3 = 0 \) along with the conditions

\[
(x_1, z_2 z_3 z_4) \neq (0,0), \quad (x_2, z_1 z_3 z_4) \neq (0,0), \quad (x_3, z_1 z_2 z_4) \neq (0,0)
\]

and

\[
(z_1, z_2) \neq (0,0), \quad (z_1, z_3) \neq (0,0), \quad (z_2, z_3) \neq (0,0)
\]

is the versal torsor of the minimal desingularisation of \( \tilde{W}_3 \) and hence, through this parametrization, we just performed a descent on the versal torsor of this minimal desingularisation of \( \tilde{W}_3 \).

2.2. The case of \( \tilde{W}_n \). Let \( n \geq 2 \). We now want to estimate, for \( B \geq 1 \), the quantity

\[
N_{\tilde{W}_n, \tilde{H}}(B) = \frac{1}{4} \# \left\{ (x, y) \in \mathbb{Z}^n \times \mathbb{Z}^n_{>0} : \begin{array}{l}
\tilde{H}(x, y) \leq B \\
(x, y) \text{ satisfy } (1.1) \\
gcd(x_1, \ldots, x_n) = gcd(y_1, \ldots, y_n) = 1
\end{array} \right\}.
\]

Clearly, we have

\[
N_{\tilde{W}_n, \tilde{H}}(B) = 2^{n-2} \# \left\{ (x, y) \in \mathbb{Z}^n \times \mathbb{Z}^n_{>0} : \begin{array}{l}
\tilde{H}(x, y) \leq B \\
(x, y) \text{ satisfy } (1.1) \\
gcd(x_1, \ldots, x_n) = gcd(y_1, \ldots, y_n) = 1
\end{array} \right\}.
\]

We can still rewrite the equation \((1.1)\) as \((2.1)\) using Lemma \( \Box \) but we can no longer deduce that \( z_{2i-1} = 1 \). We only have the divisibility relation \( z_{2i-1} | x_j \). However, we have \( z_N = 1 \).

Finally, one gets

\[
N_{\tilde{W}_3, \tilde{H}}(B) = 2 \# \left\{ (x, z) \in \mathbb{Z}^3 \times \mathbb{Z}^N_{>0} : \begin{array}{l}
\max_{1 \leq i \leq n} |x_i|^{n-1} \max_{1 \leq i \leq n} \prod_{1 \leq h \leq N-1} z_{it(h)}^{e_i} \leq B \\
\sum_{i=1}^n x_i d_i = 0 \\
gcd(x_1, \ldots, x_n) = 1, \ (z_h)_{1 \leq h \leq N-1} \text{ reduced}
\end{array} \right\}
\]

and particularly, in the case \( n = 3 \), we obtain

\[
N_{\tilde{W}_3, \tilde{H}}(B) = 2 \# \left\{ (x, z) \in \mathbb{Z}^3 \times \mathbb{Z}^6_{>0} : \begin{array}{l}
\max_{1 \leq i \leq 3} |x_i|^2 \max\{z_1 z_4 z_5, z_2 z_3 z_6, z_4 z_5 z_6\} \leq B \\
x_1 z_1 z_4 z_5 + x_2 z_1 z_4 z_6 + x_3 z_1 z_2 z_3 = 0 \\
gcd(x_1, x_2, x_3) = 1, \ (z_h)_{1 \leq h \leq 6} \text{ reduced}
\end{array} \right\}
\]

\[
2 \# \left\{ (x', z) \in \mathbb{Z}^3 \times \mathbb{Z}^6_{>0} : \begin{array}{l}
x_1' z_6 + x_2' z_5 + x_3' z_3 = 0 \\
gcd(z_1 x_1', z_2 x_2', z_4 x_3') = 1, \ (z_h)_{1 \leq h \leq 6} \text{ reduced}
\end{array} \right\}
\]

(2.3)

It is easily seen that the coprimality conditions given by \( \gcd(z_1 x_1', z_2 x_2', z_4 x_3') = 1 \), and \( (z_h)_{1 \leq h \leq 6} \) reduced are equivalent to

\[
\gcd(x_1', x_2', x_3') = \gcd(x_1', x_2', z_3) = \gcd(x_1', z_5, x_3') = \gcd(z_6, x_2', x_3') = 1
\]
together with the fact that \((z_h)_{1 \leq h \leq 6}\) is reduced. It then follows from [6] that the open subvariety of \(\mathbb{A}^6\) given by the equation \(x_1'z_6 + x_2'z_3 + x_3'z_3 = 0\) along with the conditions

\[(x_1', x_2', x_3') \neq (0, 0, 0), \quad (x_1', x_2', z_3) \neq (0, 0, 0), \quad (x_1', z_5, x_3') \neq (0, 0, 0), \quad (z_6, x_2', x_3') \neq (0, 0, 0)\]

and

\[(z_1, z_2) \neq (0, 0), \quad (z_1, z_4) \neq (0, 0), \quad (z_1, z_6) \neq (0, 0), \quad (z_2, z_4) \neq (0, 0), \quad (z_2, z_5) \neq (0, 0), \quad (z_3, z_4) \neq (0, 0), \quad (z_3, z_6) \neq (0, 0), \quad (z_5, z_6) \neq (0, 0)\]

is the versal torsor of the minimal desingularisation of \(\tilde{W}_3\) and hence, through this parametrisation, we just performed a descent on the versal torsor of this minimal desingularisation of \(\tilde{W}_3\).

### 3. Geometry and the Constant in the Case \(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1\)

We give in this section the proof of the Theorem 3. For example, [15] yields that the surface \(\tilde{W}_3\) is a del Pezzo surface of degree 6 of singularity type \(\mathbf{A}_1\) with three lines, the lines being given by

\[X_1 = X_2 = X_3 = X_5 = X_6 = 0, \quad X_1 = X_3 = X_4 = X_5 = X_6 = 0\]

and

\[X_3 = X_5 = X_6 = X_1 = X_4 = X_1 = X_2 = 0.\]

The maps \(f : \tilde{W}_3 \to S\) given by

\[
\begin{aligned}
X_1 &= -y_3x_1x_2 \\
X_2 &= -x_1(x_2y_3 + x_3y_2) \\
X_3 &= -y_2y_3x_1 \\
X_4 &= -x_2(x_1y_3 + x_3y_1) \\
X_5 &= y_1y_3x_2 \\
X_6 &= y_1y_2y_3 \\
X_7 &= x_1x_2x_3
\end{aligned}
\]

and \(g : S \to \tilde{W}_3\) given by

\[
\begin{aligned}
g([X_1 : \cdots : X_7]) &= ([X_1 : -X_5], [X_5 : X_6], [X_7 : -X_1])
\end{aligned}
\]

are well defined and inverse from each other. Thus \(\tilde{W}_3 \cong S\) and is therefore a del Pezzo surface of degree 6 of singularity type \(\mathbf{A}_1\) with three lines, the lines being given by \(y_i = y_j = 0\) for \(1 \leq i \neq j \leq 3\).

As mentioned in the introduction, it follows then from [25] and from this isomorphism that \(\tilde{W}_3\) is an equivariant compactification of \(G\) and Theorem 2 can be derived from the more general work of Chambert-Loir and Tschinkel [17]. However, the method presented here using a descent on the versal torsor is different from the method in [17] and it is always interesting to unravel a different proof.

Let us denote by \(\tilde{W}_3^*\) the minimal desingularisation of \(\tilde{W}_3\). The fact that the open subvariety \(O \subseteq \mathbb{A}^7\) given by

\[x_1z_1 + x_2z_2 + x_3z_3 = 0\]

with the conditions

\[(x_1, z_2z_3z_4) \neq 0, \quad (x_2, z_1z_3z_4) \neq 0, \quad (x_3, z_1z_2z_4) \neq 0\]

and

\[(z_1, z_2) \neq 0, \quad (z_1, z_3) \neq 0, \quad (z_2, z_3) \neq 0\]
is the versal torsor of $\tilde{W}_3^*$ is a consequence of work of Derenthal [20].

To conclude, let us briefly justify why the leading constant of Theorem 2

$$\frac{1}{144} \left( \pi^2 + 24 \log(2) - 3 \right) \prod_p \left( 1 - \frac{1}{p} \right)^4 \left( 1 + \frac{4}{p} + \frac{1}{p^2} \right)$$

agrees with Peyre’s prediction.

First of all, the variety $\tilde{W}_3$ being rational, we know that $\beta(\tilde{W}_3^*) = 1$ and work from Derenthal [20] immediately yields $\alpha(\tilde{W}_3^*) = \frac{1}{144}$. We now have that

$$\omega_H(\tilde{W}_3^*(\mathbb{A}_\mathbb{Q})) = \omega_\infty \prod_p \omega_p$$

with $\omega_p$ and $\omega_\infty$ being respectively the $p$-adic and archimedean densities. It is now easy to get that

$$\omega_p = \frac{\# O(F_p)}{p^6} = \left( 1 - \frac{1}{p} \right)^4 \left( 1 + \frac{4}{p} + \frac{1}{p^2} \right)$$

either by direct computation or by calling upon a more general result of Loughran [25]. Turning to the archimedean density and reasoning like in [7] one gets that $\omega_\infty$ is given by the archimedean density on the open subset $y_1 \neq 0$, $y_2 \neq 0$ and $y_3 \neq 0$ of $\tilde{W}_3$. This is the affine variety given by the equation

$$u_1 + u_2 + u_3 = 0.$$ 

Using a Leray form to parametrize in $u_3$, one finally obtains

$$\omega_\infty = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \frac{du_1 du_2}{\max(|u_1|, 1) \max(|u_2|, 1) \max(|u_1 + u_2|, 1)}.$$ 

An easy computation now yields

$$\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \frac{du_1 du_2}{\max(|u_1|, 1) \max(|u_2|, 1) \max(|u_1 + u_2|, 1)} = \pi^2 + 24 \log(2) - 3$$

which finally shows that the conjectural value of Peyre’s constant is

$$\alpha(\tilde{W}_3^*) \beta(\tilde{W}_3^*) \omega_H(\tilde{W}_3^*(\mathbb{A}_\mathbb{Q})) = \frac{1}{144} \left( \pi^2 + 24 \log(2) - 3 \right) \prod_p \left( 1 - \frac{1}{p} \right)^4 \left( 1 + \frac{4}{p} + \frac{1}{p^2} \right)$$

and hence that the leading constant in Theorem 2 agrees with Peyre’s prediction.

4. THE PARABOLIC EISENSTEIN SERIES AND SMOOTH APPROXIMATIONS

We quote the following lemma from [4] Lemma 4 and Remark 2].

**Lemma 2.** Let

$$(4.1) \quad A_\alpha(\alpha, \beta) := \frac{1}{8} \sum_{n_1, n_2, n_3, m_1, m_2, m_3 \in \mathbb{Z}_{\geq 0}} \frac{1}{|n_1|^{\alpha_1} |n_2|^{\alpha_2} |n_3|^{\alpha_3} |m_1|^{\beta_1} |m_2|^{\beta_2} |m_3|^{\beta_3}},$$

where $\alpha = (\alpha_1, \alpha_2, \alpha_3) \in \mathbb{Z}_{\geq 0}^3$ and $\alpha = (\alpha_1, \alpha_2, \alpha_3), \beta = (\beta_1, \beta_2, \beta_3) \in \mathbb{C}^3$ such that $R(\alpha_i), R(\beta_i) > 0$ for all $i \in \{1, 2, 3\}$. Then $A_\alpha(\alpha, \beta)$ converges absolutely if $R(\alpha_i), R(\beta_i) > \frac{2}{3}$ for all $i \in \{1, 2, 3\}$. Moreover for $\frac{2}{3} + \varepsilon < R(\alpha_i), R(\beta_i) \leq \frac{11}{12}$ it satisfies $A_\alpha(\alpha, \beta) \ll 1$ and

$$(4.2) \quad A_\alpha(\alpha, \beta) = M_\alpha(\alpha, \beta) + E_\alpha(\alpha, \beta)$$

where

$$M_\alpha(\alpha, \beta) = \sum_{\alpha^*, \beta^* \in \mathbb{C}^3 \setminus \{0\}, \forall i \in \{1, 2, 3\}} \frac{2 \sqrt{\pi} S_{\alpha^*}(\alpha^*, \beta^*) \left( \sum_{i=1}^{3} \left( 1 + \alpha_i + \alpha_{i}^* + \frac{\alpha_i^*}{\alpha_i^*} \right) \frac{\zeta(1 - \alpha_i + \alpha_i^*)}{\Gamma(1 - \alpha_i + \alpha_i^*)} \frac{\Gamma(1 + \alpha_i + \alpha_i^* + \alpha_i^*)}{\Gamma(1 + \alpha_i + \alpha_i^*)} \right)}{\alpha_i^* + \alpha_i + \alpha_3^* - 2}.$$
with
\[
S_a(\alpha^*, \beta^*) := \sum_{\ell \neq 1} \frac{(a_1, \ell)^{1-\alpha_1^*+\beta_1^*}(a_2, \ell)^{1-\alpha_2^*+\beta_2^*}(a_3, \ell)^{1-\alpha_3^*+\beta_3^*}}{\ell^{3-\sum_{i=1}^{3}(\alpha_i^* - \beta_i^*)}} \varphi(\ell),
\]
and where \(E_a(\alpha, \beta)\) is an holomorphic function on
\[
(4.3) \quad \Omega_\varepsilon := \{(\alpha, \beta) \in C^3 : \Re(\alpha_i), \Re(\beta_i) \in [\frac{5}{12}, \frac{11}{12}] \forall i \in \{1, 2, 3\}, \eta < \frac{2}{3} - \varepsilon \}
\]
for all \(\varepsilon > 0\) with \(\eta := \sum_{i=1}^{3}(|\Re(\alpha_i) - \frac{2}{3}| + |\Re(\beta_i) - \frac{2}{3}|)\). Moreover, for \((\alpha, \beta) \in \Omega_\varepsilon\) one has
\[
(4.4) \quad \|E_a(\alpha, \beta)\| \leq \left( \left( \max_{1 \leq i \leq 3} |\alpha_i| \right)^{14} \left( 1 + \max_{1 \leq i \leq 3} (|\Im(\alpha_i)| + |\Im(\beta_i)|) \right)^{21} \right)^{\frac{9\eta + 14}{10\eta}}.
\]

**Remark.** Note that the sum over \(\alpha^*, \beta^* \in C^3\) such that \(\{\alpha_i^*, \beta_i^*\} = \{\alpha_i, \beta_i\}\) for all \(i \in \{1, 2, 3\}\) appearing in the definition of the quantity \(M_a(\alpha, \beta)\) contains eight terms given by
\[
\begin{align*}
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\beta_1, \beta_2, \beta_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) = (\alpha_1, \alpha_2, \alpha_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) = (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\beta_1, \beta_2, \beta_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) = (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) = (\alpha_1, \alpha_2, \alpha_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) = (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \} \\
\{& (\alpha_1^*, \alpha_2^*, \alpha_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \quad \text{and} \quad (\beta_1^*, \beta_2^*, \beta_3^*) \neq (\alpha_1, \alpha_2, \alpha_3) \}.
\end{align*}
\]

**Proof.** Let \(a = (a_1, a_2, a_3) \in Z^3\) and \(\alpha = (\alpha_1, \alpha_2, \alpha_3), \beta = (\beta_1, \beta_2, \beta_3) \in C^3\) such that \(\Re(\alpha_i), \Re(\beta_i) > 1\) for all \(i \in \{1, 2, 3\}\). It is easy to see that \(A_a(\alpha, \beta)\) converges absolutely if \(\Re(\alpha_i), \Re(\beta_i) > \frac{2}{3}\) for all \(i \in \{1, 2, 3\}\) by alluding to inequalities of the form \(x + y \geq 2\sqrt{xy}\) for \(x, y \geq 0\).

We also clearly have
\[
A_a(\alpha, \beta) = A_{(-\varepsilon_1, \alpha_1, \varepsilon_2, \varepsilon_3, \alpha_3)}(\alpha, \beta) = A_{a, \alpha - \frac{2}{3}, \beta - \frac{4}{9}} \left( \frac{2}{9} \right).
\]
with the notations of [3] Section 2, (2.7). Therefore, [3] Lemma 4 with \(k = 3\) and \(3\varepsilon\) instead of \(\varepsilon\) implies the first part of the lemma, namely that for \(\frac{2}{3} + \varepsilon < \Re(\alpha_i), \Re(\beta_i) \leq \frac{1}{12}\) we have \(A_a(\alpha, \beta) \ll 1\) and
\[
(4.5) \quad A_a(\alpha, \beta) = M_a(\alpha, \beta) + E_a(\alpha, \beta)
\]
with \(M_a(\alpha, \beta)\) being given by the quantity \(M_{a, \alpha - \frac{2}{3}, \beta - \frac{4}{9}}\) in [3] Remark 2 with \(k = 3\) and \(E_a(\alpha, \beta)\) being defined by \(A_a(\alpha, \beta) - M_a(\alpha, \beta)\). Now, the expression at the end of [3] Remark 2 in which one has only one summand corresponding to \(I = \{1, 2, 3\}\) and \(J = 0\) in the case \(k = 3\) immediately yields the expression of \(M_a(\alpha, \beta)\) given in the statement of the lemma.

The final part of the lemma follows from [3] Theorem 3] for \(k = 3\), with \(3\varepsilon\) instead of \(\varepsilon\) and after noticing that, contrary to [4], we don’t have the fraction \(\frac{3}{2}\) in front of the sum in the definition of \(E\). Hence, in particular, \(\eta\) is given by \(\frac{3}{8}\) with the notations of [3] Theorem 3]. □

Since Lemma 2 constitutes the main tool for our proof of Theorems 1 and 2 we say a few words about its proof. First, one divides the variables \(r_i = n_im_i\) in various ranges and eliminates the largest one (say \(r_1\)) using the linear relation among them. In order to do this one has to write \(\sum_{n_1m_1=r_1} |n_1|^{-\alpha_1}|m_1|^{-\beta_1}\) in an efficient way in terms of the remaining variables. This is done by using (a shifted version of) the identity of Ramanujan for the divisor function \(\tau\) in terms of Ramanujan sums, in combination with a careful use of Mellin transforms to separate variables in expressions such as \((r_2 \pm r_3)^s\). After the variables are completely separated, one applies Voronoi’s summation formula to the sums over \(r_2\) and \(r_3\). The main terms will then give the polar structure, whereas the error term will produce functions which are holomorphic on the stated range.
The following lemma allows us to replace the characteristic function of the interval \([0, 1]\) by a smooth approximation at a cost of a controlled error.

**Lemma 3.** Let \(f(x) = e^{-1/(x-x^2)}\) for \(0 < x < 1\) and \(f(x) = 0\) otherwise. Let \(C := \int_0^1 f(y) dy\) and for \(0 \leq \delta < 1/2\), let
\[
F_\delta^{\pm}(x) := \frac{1}{\delta C} \int_x^{\pm \infty} f\left(\frac{y-1+(1 \mp 1)\delta/2}{\delta}\right) dy, \quad x \in \mathbb{R}^+.
\]
Then \(F_\delta^{\pm} \in C^\infty(\mathbb{R}^+)\), \(F_\delta^{\pm}(x) = 1\) for \(x \leq 1 - \delta\), \(F_\delta^{\pm}(x) = 0\) for \(x \geq 1 + \delta\) and, for \(x \geq 0\),
\[
0 \leq F_{\delta}^{-}(x) \leq \chi_{[0,1]}(x) \leq F_{\delta}^{+}(x),
\]
where \(\chi_{[0,1]}\) is the indicator function of the interval \([0, 1]\). Moreover, the Mellin transform \(\tilde{F}_\delta^{\pm}(s)\) of \(F_\delta^{\pm}(x)\) is holomorphic in \(\mathbb{C} \setminus \{0\}\) with a simple pole of residue one at \(s = 0\) and for all \(n \geq 0\) it satisfies for all \(s \in \mathbb{C} \setminus \{0\}\)
\[
\tilde{F}_\delta^{\pm}(s) \ll_n \frac{1}{\delta^n(1 + |s|)^{n+1}}, \quad \tilde{F}_\delta^{\pm}(s) - \frac{1}{s} \ll \min(\delta, (1 + |s|)^{-1}).
\]

**Proof.** The statements on \(F_\delta^{\pm}\) are immediate from the definitions. Moreover, assuming \(\Re(s) > 0\) and integrating by parts we have
\[
\tilde{F}_\delta^{\pm}(s) = \frac{1}{\delta C s} \int_0^{\pm \infty} x^s f\left(\frac{x-1+(1 \mp 1)\delta/2}{\delta}\right) dx = \frac{1}{s C} \int_0^1 (1 + \delta x - (1 \mp 1)\delta/2)^s f(x) dx,
\]
the last inequality resulting from a change of variable. This already shows that \(\tilde{F}_\delta^{\pm}\) is holomorphic in \(\mathbb{C} \setminus \{0\}\) with a simple pole of residue one at \(s = 0\). Integrating by parts \(n\) times then yields \(\tilde{F}_\delta^{\pm}(s) \ll_n \delta^{-n}(1 + |s|)^{-n-1}\), which also implies the second bound in \((4.6)\) if \(\delta \geq 1/|s|\). Finally, if \(\delta < 1/|s|\) we have
\[
\tilde{F}_\delta^{\pm}(s) - \frac{1}{s} = \frac{1}{s C} \int_0^1 ((1 + \delta x - (1 \mp 1)\delta/2)^s - 1) f(x) dx \ll \delta
\]
since \((1 + x)^s = 1 + O(|sx|)\) for \(|sx| < 1\), \(|x| \leq \frac{1}{2}\). \(\square\)

5. PROOF OF THEOREM 2 NEGLCETING THE COPRIMALITY CONDITIONS

By Section 2.1 we need to count the integer solutions to
\[
(5.1) \quad x_1z_1 + x_2z_3 + x_3z_3 = 0
\]
satisfying the inequality \(\max\{|x_1|, z_2z_3z_4\} \times \max\{|x_2|, z_1z_3z_4\} \times \max\{|x_3|, z_1z_2z_4\} \leq B\) and the coprimality conditions
\[
(5.2) \quad \gcd(z_1, z_2) = \gcd(z_1, z_3) = \gcd(z_2, z_3) = 1, \quad \gcd(x_1, z_2z_3z_4) = \gcd(x_2, z_1z_3z_4) = \gcd(x_3, z_2z_3z_4) = 1
\]
with \(z_1, z_2, z_3, z_4 > 0\). The case where \(x_1x_2x_3 = 0\) can be dealt with easily and we postpone its treatment to section 6 so we focus on the case where \(x_1x_2x_3 \neq 0\). We start with the following proposition which gives an asymptotic formula for the number of solutions to the more general equation
\[
a_1x_1z_1 + a_2x_2z_3 + a_3x_3z_3 = 0
\]
without imposing any coprimality condition. These conditions do not factor out immediately at the beginning of the argument, so one cannot deduce Theorem 2 directly from the Proposition 1, however it is instructive to prove this result first, as all the analytic difficulties are exactly the same but the notations and the arithmetic are simplified. In Section 6 we shall give the proof of Theorem 2 by performing the required arithmetic computations and indicating the minor differences in the analytic argument.
**Proposition 1.** Let $B \geq 1$ and $\varepsilon > 0$. Let $a = (a_1, a_2, a_3) \in \mathbb{Z}_{\neq 0}^3$ and

\begin{equation}
K_a(B) := \# \left\{ (x, z) \in \mathbb{Z}_0^3 \times \mathbb{Z}_0^4 \mid a_1x_1z_1 + a_2x_2z_2 + a_3x_3z_3 = 0 \right. \\
\left. \max\{|x_1|, |x_2|, |x_3|, z_1z_2z_3z_4| \leq B \right\}.
\end{equation}

Then there exists a polynomial $P_a$ of degree 3 such that

\begin{equation}
K_a(B) := BP_a(\log B) + O_\varepsilon \left( B^{296 + \varepsilon} \max_{1 \leq i \leq 3} |a_i|^{14} \right),
\end{equation}

where the implied constant only depends on $\varepsilon$. The coefficients of the polynomial $P_a$ are $O(\max_{1 \leq i \leq 3} |a_i|^5)$ and the leading coefficient is $\frac{1}{111} I_a G'_a$, where

\begin{equation}
I_a := \int \int_{[-0.1, 0.1]^3 \times [0, 1]^2} \chi_{[0, a_3/\varepsilon]}(a_1 \frac{x_1}{y_1} + a_2 \frac{x_2}{y_2}) \, dx_1 \, dx_2 \, dz_1 \, dz_2 \, dy_1 \, dy_2
\end{equation}

and

\begin{equation}
G'_a := \sum_{\ell=1}^{\infty} \frac{(a_1, \ell)(a_2, \ell)(a_3, \ell) \varphi(\ell)}{\ell^3}.
\end{equation}

**Proof.** In the set defining $K_a(B)$ we have 8 inequalities coming from all the possible values taken by the maxima. In other words, given each subset $I \subseteq S_3 := \{1, 2, 3\}$ we have the condition

\[
\frac{(z_1z_2z_3z_4)^{|J|}}{B} \prod_{i \in I} |x_i| \prod_{j \in J} z_j^{-1} \leq 1
\]

where $J := S_3 \setminus I$. Now, let $0 < \delta < \frac{1}{2}$ and $F_\delta^{\pm}$ be as in Lemma 3. Then we have $K_a^-(B) \leq K_a(B) \leq K_a^+(B)$, where

\[
K_a^{\pm}(B) := \sum_{(a, s) \in \mathbb{Z}_{\neq 0}^3 \times \mathbb{Z}_{\neq 0}^4 \atop a_1x_1z_1 + a_2x_2z_2 + a_3x_3z_3 = 0} \prod_{I \subseteq S_3} F_\delta^{\pm} \left( \frac{(z_1z_2z_3z_4)^{|J|}}{B} \prod_{i \in I} |x_i| \prod_{j \in J} z_j^{-1} \right).
\]

Clearly it is sufficient to show that (5.3) holds for both $K_a^-(B)$ and $K_a^+(B)$ with the same polynomial $P$. We now write each $F_\delta^{\pm}$ in terms of its Mellin transform using the variable $s_I$ for the cut-off function corresponding to the set $I$. For brevity we shall often indicate for example with $s_{123}$ the variable $s_{(1, 2, 3)}$ and with $c_{1(2, 3)}$ or $c_{123}$ the corresponding line of integration, and similarly for the other variables. In particular, we will denote by $s$ the variable $s_0$. As lines of integration, we take $c_I = \frac{|I|}{12} + \varepsilon$ for all $I$ for a fixed $\varepsilon > 0$ small enough. Doing so we obtain

\[
K_a^{\pm}(B) = \sum_{(a, s) \in \mathbb{Z}_{\neq 0}^3 \times \mathbb{Z}_{\neq 0}^4 \atop a_1x_1z_1 + a_2x_2z_2 + a_3x_3z_3 = 0} \frac{1}{(2\pi i)^3} \int \int_{(c_I)} \frac{B s_I}{x_4} \prod_{i \in I} |x_i|^{-|I|} \prod_{i \in I} z_i^{-|I|} \prod_{i \in I} s_i(2 + \delta_i)|I| \prod_{I} F_\delta^{\pm}(s_I) \, ds_I
\]

where $\delta_i = 1$ if $i \in I$ and $\delta_i = 0$ otherwise and where the sums inside the integrals are over $I \subseteq S_3$. Notice that with this choice we have

\[
\sum_{I \subseteq S_3} c_I = 1 + 8\varepsilon, \quad \sum_{I \subseteq S_3} c_I = \frac{2}{3} + 4\varepsilon, \quad \sum_{I \subseteq S_3} c_I(2 + \delta_i) = \frac{2}{3} + 8\varepsilon, \quad \sum_{I \subseteq S_3} c_I(3 - |I|) = 1 + 12\varepsilon.
\]
In particular the above series are absolutely convergent by Lemma 2. Now, write
\[\xi := \frac{1}{2}(2s + s_1 + s_2 + s_3 - s_{123})\]
\[\alpha_1 := \frac{1}{2}(2s + 3s_1 + s_2 + s_3 + 2s_{12} + 2s_{13} + s_{23}) = \sum_{l \leq I} s_l + \xi = \sum_{l} s_l (2 + \delta_{1l} - |I|) - \xi\]
\[\alpha_2 := \frac{1}{2}(2s + s_1 + 3s_2 + s_3 + 2s_{12} + 2s_{23} + s_{13}) = \sum_{2 \leq I} s_l + \xi = \sum_{l} s_l (2 + \delta_{2l} - |I|) - \xi\]
\[\alpha_3 := \frac{1}{2}(2s + s_1 + s_2 + 3s_3 + 2s_{13} + 2s_{23} + s_{12}) = \sum_{3 \leq I} s_l + \xi = \sum_{l} s_l (2 + \delta_{3l} - |I|) - \xi\]
where we are neglecting here the dependencies on the variables \(s_l\) in the notations in order to simplify the exposition. Notice then that
\[\sum_{l \leq S_3} s_l = \frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 - \xi), \quad \sum_{l \leq S_3} s_l (3 - |I|) = \frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi).
\]
Thus, summing the Dirichlet series we have
\[K^\pm_a(B) = \frac{1}{(2\pi i)^8} \int_{(c_1)} B^2(\alpha_1 + \alpha_2 + \alpha_3 - \xi)(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi))A_a(\alpha - \xi, \alpha + \xi) \prod_l \tilde{F}^\pm_l(s_l)ds_l
\]
with the notation of Lemma 2. By Lemma 2 and using the notations (4.5), we can split \(A_a(\alpha - \xi, \alpha + \xi)\) into
\[A_a(\alpha - \xi, \alpha + \xi) = M_a(\alpha - \xi, \alpha + \xi) + E_a(\alpha - \xi, \alpha + \xi)
\]
thus obtaining the corresponding decomposition \(K^\pm_a(B) = M^\pm_a(B) + E^\pm_a(B)\), with
\[M^\pm_a(B) := \frac{1}{(2\pi i)^8} \int_{(c_1)} B^2(\alpha_1 + \alpha_2 + \alpha_3 - \xi)(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi))M_a(\alpha - \xi, \alpha + \xi) \prod_l \tilde{F}^\pm_l(s_l)ds_l
\]
and
\[E^\pm_a(B) := \frac{1}{(2\pi i)^8} \int_{(c_1)} B^2(\alpha_1 + \alpha_2 + \alpha_3 - \xi)(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi))E_a(\alpha - \xi, \alpha + \xi) \prod_l \tilde{F}^\pm_l(s_l)ds_l.
\]
In the latter integral we move the line of integration \(c_{S_3}\) to \(c_{S_3} = \frac{1}{3} - \frac{\varepsilon}{27} + 6\varepsilon = \frac{10}{27} + 6\varepsilon\). Notice that doing so, in the new lines of integration, we have \(\mathbb{R}(\alpha_i + \xi) = \frac{2}{3} + 8\varepsilon\) and \(\mathbb{R}(\alpha_i - \xi) = \frac{2}{3} - \frac{2}{27} + 9\varepsilon = \frac{16}{27} + 9\varepsilon\) for all \(i \in \{1, 2, 3\}\). In particular we have \(\eta = \sum_{i=1}^3 (|\mathbb{R}(\alpha_i - \xi) - \frac{2}{3}| + |\mathbb{R}(\alpha_i + \xi) - \frac{2}{3}|) = \frac{2}{3} - 3\varepsilon\) on the new lines of integration. Moreover, since
\[\frac{\alpha_1 + \alpha_2 + \alpha_3 + 3\xi}{2} = 3s + 2(s_1 + s_2 + s_3) + s_{12} + s_{13} + s_{23}
\]
is independent of \(s_{123}\), we have \(\mathbb{R}(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi)) = 1 + 12\varepsilon\) on the range \(\frac{19}{108} + 6\varepsilon \leq s_{S_3} \leq \frac{1}{4} + \varepsilon\) and hence we stay on the right of the pole of the \(\zeta\)-function. By (4.4) we then have for \(\varepsilon\) small enough,
\[E^\pm_a(B) \leq A^{14}B^{\frac{35}{2} + 13\varepsilon} \int_{(c_1)} (1 + \max |s_l|)^{21} \prod_l |\tilde{F}^\pm_l(s_l)|ds_l
\]
where \(A := \max_{1 \leq i \leq 3} |a_i|\). Now, we have
\[\int_1^{+\infty} \min \left(\frac{1}{x}, \frac{1}{x^{1/2}}\right)dx \ll |\log \delta| \ll \varepsilon \delta^{-\varepsilon},\]
\[\int_1^{+\infty} x^{21} \min \left(\frac{1}{x}, \frac{1}{x^{22}}, \frac{1}{x^{23}}\right)dx \ll \int_1^{1/\delta} x^{20} dx + \delta^{-22} \int_{1/\delta}^{+\infty} x^{-2} dx \ll \delta^{-21}
\]
and so, using Lemma 3 we find
\[E^\pm_a(B) \ll A^{14}B^{\frac{35}{2} + 13\varepsilon} \delta^{-21 - \varepsilon}.
\]
Now, we consider the main term $M_a^+(B)$ defined in (5.7). We can write $M_a(\alpha - \xi, \alpha + \xi)$ as

$$M_a(\alpha - \xi, \alpha + \xi) = \sum_{k=0}^{3} \frac{\zeta(1 + 2\xi)^k\zeta(1 - 2\xi)^{3-k}}{a_1 + a_2 + a_3 + (3 - 2k)\xi - 2} Q_{a,k}(\alpha, \xi)$$

with

$$Q_{a,k}(\alpha, \xi) := \sum_{\epsilon \in \{\pm 1\}^3} \sum_{\ell=1}^{+\infty} \frac{(a_1, \ell)^{1+2\xi}(a_2, \ell)^{1+2\xi}(a_3, \ell)^{1+2\xi}}{\ell^{3+2(k-3)\xi}} \phi(\ell)$$

(5.11)

and where the sum is over $\epsilon = (\epsilon_1, \epsilon_2, \epsilon_3) \in \{\pm 1\}^3$. Notice that in the region

$$0 \leq \Re(-\alpha_i + \epsilon_i \xi + \frac{1 + \alpha_1 + \alpha_2 + \alpha_3 + (3 - 2k)\xi}{3}) \leq \frac{1}{2} \quad \forall i \in \{1, 2, 3\}, \quad |\Re(\xi)| \leq \frac{1}{3} - \epsilon$$

we have that $Q_{a,k}(\alpha, \xi)$ is holomorphic and satisfies

(5.13) \quad $Q_{a,k}(\alpha, \xi) \ll A^{3+6\Re(\xi)}$

uniformly in $a$, by the bound $|(a, \ell)^s/\ell^s| \leq (|a|/\ell)^{\Re(s)}$ for $\Re(s) \geq 0$, and since

(5.14) \quad $\Gamma(s)/\Gamma(\frac{1-s}{2}) \ll (1 + |s|)^{s-\frac{1}{2}}$

by Stirling’s formula [23] (8.328.1)].

Then, we write $M_a^+(B) = \sum_{k=0}^{3} M_{a,k}^+(B)$ where

$$M_{a,k}^+(B) = \frac{1}{(2\pi i)^8} \int_{(c)} B^\frac{1}{2}(a_1+a_2+a_3-\xi)\zeta\left(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi)\right) \frac{\zeta(1 + 2\xi)^k\zeta(1 - 2\xi)^{3-k}}{\alpha_1 + \alpha_2 + \alpha_3 + (3 - 2k)\xi - 2}$$

$$\times Q_{a,k}(\alpha, \xi) \prod_l \hat{F}_l^+(s_l) ds_I$$

and with all the lines of integration still at $c_I = \frac{|I|}{12} + \epsilon$ for all $I$. If $k \in \{0, 1\}$ we move the line of integration $c_{S_1}$ and $c_0$ to $c_{S_3} = \frac{1}{3} - \frac{\pi}{12} + \epsilon$ and $c = \frac{2}{3} + \epsilon$ without passing through any pole. Indeed, by (5.8), we have

$$1 + 12\epsilon \leq \Re\left(\frac{1}{2}(\alpha_1 + \alpha_2 + \alpha_3 + 3\xi)\right) \leq \frac{29}{27} + 12\epsilon$$

and $\Re(s) = \Re(s) - \frac{\Re(s_{123})}{2} + \frac{1}{3} + \frac{3}{2} \epsilon$ satisfies $\Re(\xi) \geq 2\epsilon$ in the range $\frac{1}{4} + \epsilon \leq c_{S_1} \leq \frac{49}{122} + \epsilon$ and $\epsilon \leq c_0 \leq \frac{2}{3} + \epsilon$. Thus, for $k \in \{0, 1\}$ we have

(5.15) \quad $M_{a,k}^+(B) \ll A^{\frac{1}{2}+12\epsilon} B^{\frac{1}{2}+4\epsilon} \int_{(c)} (1 + \max |s_I|) \prod_l |\hat{F}_l^+(s_l)| ds_I \ll A^{\frac{1}{2}+12\epsilon} B^{\frac{1}{2}+8\epsilon} \delta^{-1-\epsilon}$

since we are inside the region (5.12) and since $|\zeta(1 - 2\xi)|^3 \ll 1 + |\xi|$ for $\Re(\xi) = \frac{2}{3} + \epsilon$ by the convexity bound [23] (5.1.4).

Now, consider the case $k \in \{2, 3\}$. In those cases and for $\epsilon$ small enough we move the line of integration $c_{S_1}$ to $c_{S_3} = \frac{10}{108} + \epsilon$ passing through the pole at $\alpha_1 + \alpha_2 + \alpha_3 + (3 - 2k)\xi - 2 = 0$, namely $s_{123} = \frac{2}{k} - \frac{1}{k} \sum_{l \neq 3} s_{l}((2 - |I|)(3 - k) + |I|) s_I$ with respect to $s_{123}$, but without crossing the poles of the $\zeta$ functions by (5.8) and since we increased $\Re(\xi)$ from $2\epsilon$ to $\frac{2}{3} + 2\epsilon$. The contribution of the integral on the new lines of integration is easily seen to be $O\left(A^{\frac{2}{3}+12\epsilon} B^{\frac{2}{3}+8\epsilon} \delta^{-1-\epsilon}\right)$ and so we are left with examining the contribution of the residue.
First we consider the case $k = 2$. As mentioned above, with respect to $s_{123}$ the pole is located at $s_{123} := 1 - \sum_{I \neq S} s_I$. Also, we can replace each $\tilde{F}^\pm_\delta(s_I)$ with $\frac{1}{s_I}$ at a cost of committing an error which, by \eqref{4.6} and \eqref{5.13} since \eqref{5.12} is satisfied, is bounded by

$$B \max_{I' \leq S} \int_{(c_I)_{I' \neq S}} A^{3+6\Re(\xi)}|\zeta(1-2\xi)| \min\left(\frac{1}{|s_{I'}|}, \frac{1}{|s_I|}, \prod_{I \neq S} |s_I| / \prod_{I \neq S} ds_I\right)$$

where $s_{123} := 1 - \sum_{I \neq S} s_I$. In particular, $\Re(s_{123}) = \frac{1}{3} - 7\varepsilon$. Also, $\Re(\xi) = 6\varepsilon$ and so $|\zeta(1-2\xi)| \ll |\xi|^{7\varepsilon}$ by the convexity bound \eqref{32} (5.14). Thus, the above is, for $I' \neq S$,

\begin{equation}
\ll B \int_{(c_I)_{I' \neq S}} \frac{\delta^{3+36\varepsilon} B \max_{I} |s_I|^{7\varepsilon}}{|1 - \sum_{I \neq S} s_I|} \prod_{I \neq S} \frac{1}{|s_I|} \prod_{I \neq S} ds_I + \int_{(c_I)_{I' \neq S}} \frac{\delta^{3+36\varepsilon} B \max_{I} |s_I|^{7\varepsilon}}{|1 - \sum_{I \neq S} s_I|} \prod_{I \neq S} \frac{1}{|s_I|} \prod_{I \neq S} ds_I
\end{equation}

and a similar argument gives the same bound also for $I = S$. It follows that

\begin{equation}
M_{a,2}^+(B) = W_a B + O\left(A^{\frac{31}{2} + 12\varepsilon} B^{\frac{5}{2} + 8\varepsilon} \delta^{-1-\varepsilon} + A^{3+36\varepsilon} B^{1+4\varepsilon} \delta^{-1-8\varepsilon}\right)
\end{equation}

where

\begin{equation}
W_a := \frac{1}{(2\pi i)^2} \int_{(c_I)_{I' \neq S}} \frac{\zeta(1+2\xi)^3 \zeta(1-2\xi)}{2(1 - \sum_{I \neq S} s_I)} Q_{a,2}(\alpha, \xi) \prod_{I \neq S} \frac{ds_I}{s_I}
\end{equation}

and where $\alpha$ and $\xi$ are given by \eqref{5.6} with $s_{123}$ replaced by $1 - \sum_{I \neq S} s_I$. Notice that by \eqref{5.13}, we have $W_a \ll \delta^5$.

Now, let us consider the case $k = 3$. We proceed as above replacing $\tilde{F}^\pm_\delta(s_I)$ by $s_I^{-1}$ for all $I \neq \emptyset$. We can’t do the same for $I = \emptyset$ yet because the pole giving the residue is, for $\varepsilon$ small enough, at $s_{123} = \frac{2}{3} - \frac{1}{3} \sum_{I \neq S} |I| s_I$ with respect to $s_{123}$ which does not depend on $s$ and thus the integral with $\tilde{F}^\pm_\delta(s)$ replaced by $1/s$ is not absolutely convergent. We arrive to

\begin{equation}
M_{a,3}^+(B) = \frac{1}{(2\pi i)^2} \int_{(c_I)_{I' \neq S}} B^{1+\xi} \zeta(1+3\xi)^3 \zeta(1+2\xi)^3 \prod_{I \neq S} \frac{Q_{a,3}(\alpha, \xi) s \tilde{F}^\pm_\delta(s)}{|s| I_s} ds_I \prod_{I \neq S} \frac{ds_I}{s_I}
\end{equation}

where the lines of integration are still at $c_I = \frac{|I|}{12} + \varepsilon$ for all $I \neq S$. Next, we move the lines of integration $c_I$ to $c_I = \varepsilon$ for all $I$ satisfying $|I| = 1$. This has the effect of moving $\Re(\xi)$ from $4\varepsilon$ to $-\frac{1}{6} + 4\varepsilon$ and $\Re(\zeta) - \frac{3}{2} \sum_{I \neq S} |I| s_I$ from $\frac{1}{3} - 3\varepsilon$ to $\frac{1}{3} - 3\varepsilon$. In particular we stay on the right of the poles at $s_I = 0$ for all $I$ and we encounter a quadruple pole at $s := \frac{1}{3} - \frac{1}{3} \sum_{I \neq \emptyset, S} (3 - |I|) s_I$ with respect to $s$. Note that we have $\xi = 0$ at the quadruple pole. The contribution of the integrals on the new lines of integration is, as in \eqref{5.9}

$$\ll A^{2+24\varepsilon} B^{\frac{5}{2} + 4\varepsilon} \int_{(c_I)_{I' \neq S}} \frac{\max_{I} |s_I|^{\frac{3}{2}}}{|2 - \sum_{I \neq S} |I| s_I|} |s \tilde{F}^\pm_\delta(s)| \prod_{I \neq S} \frac{ds_I}{|s_I|} \ll A^{2+24\varepsilon} B^{\frac{5}{2} + 4\varepsilon} \delta^{-\frac{1}{2} - \varepsilon},$$

since we are on the region \eqref{5.12} and since, by the convexity bound \eqref{32} (5.14), $|\zeta(1+3\xi)^3 |(1+2\xi)^3| \ll |\xi|^{\frac{3}{2}}$ for $\Re(\xi) = -\frac{1}{6} + 4\varepsilon$. As for the residue, we notice that we can replace $s \tilde{F}^\pm_\delta(s)$ by $1$ at a cost of an error which is $O(\delta A^{3+6\varepsilon} B^{1+5\varepsilon})$. Indeed, we can write the residue as an integral in $s$ along a circle of radius $\varepsilon$ around $\frac{1}{3} - \frac{1}{3} \sum_{I \neq \emptyset, S} (3 - |I|) s_I = O(\varepsilon)$. We then use $s \tilde{F}^\pm_\delta(s) - 1 = O(|s| \delta)$ coming from
and bound trivially the integrals. Thus, we have
\[ M_{a,3}^\pm(B) = \frac{1}{(2\pi i)^6} \int_{|c_I| \neq s_3} \text{Re} \left( B^{1+\xi} \frac{(1+3\xi)\zeta(1+2\xi)^3}{3s_{123} s} Q_{a,3}(\alpha, \xi) \right) \prod_{I \neq \emptyset, \emptyset} ds_I s_I^{-1} \]
\[ + O \left( B^{\frac{13}{6} + 8s_5\delta^{-1-\varepsilon} + B^{1+5\delta}} \right) \]
with
\[ s := \frac{1}{3} - \frac{1}{3} \sum_{I \neq \emptyset, \emptyset} (3 - |I|) s_I, \quad s_{123} := \frac{2}{3} - \frac{1}{3} \sum_{I \neq \emptyset, \emptyset} |I| s_I, \]
\[ \alpha \text{ given by (5.6) with } s_{123} \text{ and } s \text{ replaced by (5.18) and lines of integration which we can take to be } c_I = \frac{1}{12} \text{ for all } I \neq S_3, \emptyset. \]
Note that computing the residue in \( \xi \) rather than in \( s \) doesn’t change the result. Computing the residue then gives
\[ M_{a,3}^\pm(B) = BP_a(\log B) + O \left( A^{\frac{13}{12} + 12\varepsilon} B^{\frac{13}{6} + 8s_5\delta^{-1-\varepsilon} + A^{13} + 36\varepsilon - 1-7\varepsilon} \right), \]
where \( P_a \) is a degree 3 polynomial with leading coefficient
\[ P_{a,3} := \frac{1}{(2\pi i)^6} \int_{|c_I| \neq s_3} \frac{Q_{a,3}(\alpha, 0)}{432 s_{123} s} \prod_{I \neq \emptyset, \emptyset} ds_I s_I^{-1} \]
with \( s \) and \( s_{123} \) given by (5.18).

(5.21)
\[ \alpha_2 = \frac{1}{3}(2 + 2s_2 - s_1 - s_3 + s_{12} + s_{23} - 2s_{13}), \quad \alpha_3 = \frac{1}{3}(2 + 2s_3 - s_1 - s_2 + s_{13} + s_{23} - 2s_{12}), \]
and \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \), where again we neglect the dependencies on \( s_I \) for \( I \neq \emptyset, S_3 \) in the notations. Note that we will establish later that \( P_{a,3} = \frac{1}{144} T_a \mathcal{F}_a' \) with the notations of Proposition 1 and hence \( P_{a,3} \neq 0 \). Also, by (5.13) and the corresponding bound for the derivatives of \( Q_{a,k}(\alpha, \xi) \) with respect to \( \xi \), we have that the coefficients of \( P_{a,3} \) are \( O(A^5) \).

Collecting the estimates (5.10), (5.15), (5.17) and (5.19) we have
\[ K_{a}^\pm(B) = BP_a(\log B) + W_a B + O \left( A^{3+36\varepsilon} B^{1+5\varepsilon\delta^{-1-\varepsilon} + A^{14} B^{\frac{13}{6} + 14\varepsilon}} \right) \]
\[ = BP_a(\log B) + W_a B + O \left( A^{14} B^{\frac{13}{6} + 14\varepsilon} \right), \]
on upon choosing \( \delta = B^{-\frac{1}{12}} \). Thus, it remains to show that \( P_{a,3} = \frac{1}{144} T_a \mathcal{F}_a' \) with the notations of Proposition 1.

First, we notice that, for \( \alpha_1 + \alpha_2 + \alpha_3 = 2 \) and \( \xi = 0 \), \( Q_{a,3}(\alpha, \xi) \) simplifies to
\[ Q_{a,3}(\alpha, 0) = 2\pi^\frac{1}{2} \mathcal{F}_a' 3 \prod_{i=1}^{3} \frac{\Gamma(\frac{1-\alpha_i}{2})}{\Gamma(\frac{3}{2})}. \]
Next, we use \( \alpha_2, \alpha_3 \) as new variables, writing \( s_2 \) and \( s_3 \) as
\[ s_2 = -2 + 2\alpha_2 + \alpha_3 + s_1 + s_{13} - s_{23}, \quad s_3 = -2 + 2\alpha_3 + \alpha_2 + s_1 + s_{12} - s_{23}. \]
Note that with this change of variables, we also have
\[ s_{123} = 2 - \alpha_2 - \alpha_3 - s_1 - s_{12} - s_{13}, \quad s = 3 - 2\alpha_2 - 2\alpha_3 - 2s_1 - s_{12} - s_{13} + s_{23} \]
and remind that \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \). The lines of integration for \( \alpha_2, \alpha_3 \) are at real part equal to \( \frac{3}{4} \). Since the Jacobian of the above change of variables is equal to 3 we find, with (5.22) and (5.23)
\[ P_{a,3} = \frac{1}{(2\pi i)^7} \int_{|\xi| \neq \frac{1}{2}} Q_{a,3}(\alpha, 0) \frac{1}{(2\pi i)^4} \int_{|\xi| \neq \frac{1}{2}} \frac{ds_1 ds_2 ds_{13} ds_{23}}{144 s_{123} s_2 s_1 s_{12} s_{13} s_{23}} do_2 do_3. \]
The inner integrals can be evaluated by moving each integral to \( -\infty \) (or, equivalently, to \( +\infty \)), repeatedly applying the residue theorem. For example, one can start by moving \( c_{s_1} \) to \( -\infty \) encountering
poles at \( s_1 = 0, s_1 = 2 - 2\alpha_2 - \alpha_3 - s_2 - s_13 + s_{23} \) and \( s_1 = 2 - 2\alpha_3 - \alpha_2 - s_3 - s_{12} + s_{23} \). Inserting the contribution of the residues and moving the remaining integrals in the same way one finds, after a simple but tedious calculation which can be readily checked using Mathematica, that

\[
P_{a,3} = \frac{1}{(2\pi i)^2} \int \frac{-Q_{a,3}(\alpha, 0)}{144\alpha_1\alpha_2\alpha_3(\alpha_1 - 1)(\alpha_2 - 1)(\alpha_3 - 1)} \, \, d\alpha_2 d\alpha_3
\]

\[
= \frac{\mathcal{S}_a'}{(2\pi i)^2} \int \frac{2\pi^2}{144} \prod_{i=1}^{3} \frac{\Gamma\left(\frac{1-\alpha_i}{2}\right)}{\alpha_i(1-\alpha_i)|\alpha_i|^{1-\alpha_i}\Gamma\left(\frac{\alpha_i}{2}\right)} \, \, d\alpha_2 d\alpha_3
\]

with \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \) and the result follows by the following lemma.

**Lemma 4.** For \( a \in \mathbb{Z}^3 \neq 0 \) we have

\[
(5.24) \quad \mathcal{I}_a = \frac{1}{(2\pi i)^2} \int \frac{\Gamma\left(\frac{1-\alpha_i}{2}\right)}{\Gamma(\frac{\alpha_i}{2})} \prod_{i=1}^{3} \frac{\Gamma\left(\frac{1-\alpha_i}{2}\right)}{\Gamma\left(\frac{\alpha_i}{2}\right)} \, \, d\alpha_2 d\alpha_3
\]

where \( \alpha_1 := 2 - \alpha_2 - \alpha_3 \). Moreover, \( \mathcal{I}_a = \pi^2 + 24\log 2 - 3 \).

**Proof.** For \( \alpha_1 + \alpha_2 + \alpha_3 = 2 \), we have the \( \Gamma \) identity (see (2.8) in [3])

\[
\pi^2 \prod_{i=1}^{3} \frac{\Gamma\left(\frac{1-\alpha_i}{2}\right)}{\Gamma(\frac{\alpha_i}{2})} = \sum_{i=1}^{3} \frac{\Gamma(1-\alpha_i)\Gamma(1-\alpha_2)\Gamma(1-\alpha_3)}{\Gamma(1-\alpha_i)\Gamma(1-\alpha_i)}
\]

and, considering \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \) as a function of \( \alpha_2 \) with \( \alpha_3 \) fixed, we have the Mellin transforms [3] (7.7.9) and (7.7.14-15) for \( x > 0 \)

\[
(5.25) \quad \frac{1}{2\pi i} \int_{(c)} \frac{\Gamma(1-\alpha_1)\Gamma(1-\alpha_2)\Gamma(1-\alpha_3)}{\Gamma(1-\alpha_i)\Gamma(\alpha_i)} x^{\alpha_2-1} \, \, d\alpha_2 = \begin{cases} (1-x)^{-\alpha_3}\chi_{[0,1]}(x) & \text{if } i = 1 \\ (x-1)^{-\alpha_3}\chi_{[1,\infty)}(x) & \text{if } i = 2 \\ (1+x)^{-\alpha_3} & \text{if } i = 3 \end{cases}
\]

for \( c > 0 \) and \( \Re(\alpha_3) < 1 \) if \( i = 1, c > 0, \Re(\alpha_3) > 0 \) if \( i = 2 \) and \( 0 < c < \Re(\alpha_3) \) if \( i = 3 \). Also, for \( 0 < \Re(\alpha_2), \Re(\alpha_3) < 1 \), we have the identity

\[
\int_{[0,1]^4} (x_1/y_1)^{1-\alpha_2-\alpha_3}(x_2/y_2)^{\alpha_2-1}(y_1 y_2)^{-1} \, \, dx_1 dx_2 dy_1 dy_2 = \frac{1}{\alpha_1(\alpha_1 - 1)\alpha_2(\alpha_2 - 1)}
\]

It follows that, in the case \( i = 1 \),

\[
\frac{1}{(2\pi i)^2} \int_{(z)} \frac{\Gamma(1-\alpha_1)\Gamma(1-\alpha_2)\Gamma(1-\alpha_3)}{\alpha_1\alpha_2\alpha_3(1-\alpha_1)(1-\alpha_2)(1-\alpha_3)\Gamma(\alpha_1)} \, \, d\alpha_2 d\alpha_3
\]

\[
= \int_{|x_1+x_1/y_2| > 0} \frac{1}{2\pi i} \int_{(z)} \frac{(|a_1|x_1/y_1 - |a_2|x_2/y_2)^{-\alpha_3}|a_3|^{\alpha_3-1}}{\alpha_3(1-\alpha_3)} \, \, d\alpha_3(y_1 y_2)^{-1} dx_1 dx_2 dy_1 dy_2
\]

\[
= \int_{0 \leq |a_1| |x_1+x_1/y_2| < |a_2|} (|a_3|y_1 y_2)^{-1} dx_1 dx_2 dy_1 dy_2 dz,
\]

since \( \frac{1}{2\pi i} \int_{(z)} x^{-\alpha} \frac{dx}{\Gamma(\alpha)} = \int_0^1 \chi_{[0,1/2]}(x) \, \, dx \), for \( x > 0 \). One evaluates similarly the cases arising from \( i \in \{2, 3\} \) and (5.24) easily follows.

Finally, in the case where \( a = (1, 1, 1) \), we notice that after using the Gamma identity \( \cos\left(\frac{\alpha_1}{2}\right)\Gamma(s) = \)
\[ \pi^{1/2} \Gamma \left( \frac{x}{2} \right) / \Gamma \left( \frac{1-x}{2} \right), \] which follows from the reflection and duplication formulae for the Gamma function, the integral on the right hand side of [5.24] reduces to

\[ \frac{8}{\pi} \times \frac{1}{(2\pi)^2} \int \cdots \int \frac{\pi(1-\alpha_i) \cos \left( \frac{\pi(1-\alpha_i)}{2} \right)}{\alpha_i(1-\alpha_i)} \, \text{d}z_2 \text{d}z_3 \]

\[ = \frac{8}{\pi} \times \frac{1}{(2\pi)^2} \int \cdots \int \frac{\Gamma(z_1) \Gamma(z_2) \Gamma(1-z_1-z_2) \cos \left( \frac{\pi z_1}{2} \right) \cos \left( \frac{\pi z_2}{2} \right) \cos \left( \frac{\pi(1-z_1-z_2)}{2} \right)}{z_1 z_2 (1-z_1-z_2) (1-z_1) (1-z_2) (z_1+z_2)} \, \text{d}z_1 \text{d}z_2 \]

after the change of variables \( z_1 = \alpha_2 \) and \( z_2 = \alpha_3 \) and remembering that \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \). The last integral above is computed in Lemma 2.10 of [8], where it was shown to be equal to \( \pi^2 + 24 \log 2 - 3 \) by means of a long calculation. One could also give a shorter proof of this identity (still requiring some computations) by writing \( (\alpha_1(\alpha_1-1)\alpha_2(\alpha_2-1))^{-1} \) in terms of its (1-variable) Mellin transform, applying [5.25] and evaluating the resulting integrals. \( \square \)

### 6. Proof of Theorem 2

We now move to the proof of Theorem 2, namely counting points satisfying [5.1] and the coprimality conditions [5.2]. First, we give three lemmata which respectively remove the extra coprimality conditions by mean of Möbius inversion formula, show the convergence of the resulting sums, and compute the Euler product arising in the main term.

**Lemma 5.** Let \( f : \mathbb{R}^7 \to \mathbb{C} \) a function of compact support. Then,

\[
\sum_{(x,z) \in \mathbb{Z}_{\geq 0}^7}^\prime f(x_1, z_1, x_2, z_2, x_3, z_3, z_4) \mu(e, d, \ell) = \sum_{(x,z) \in \mathbb{Z}_{\geq 0}^7}^\prime f(b_1 x_1, c_1 z_1, b_2 x_2, c_2 z_2, b_3 x_3, c_3 z_3, c_4 z_4),
\]

where here and below \( \sum^\prime \) indicates that the sum is restricted to satisfy the coprimality conditions

\[
(z_1, z_2) = (z_1, z_3) = (z_2, z_3) = 1, \quad (x_1, z_2 z_3 z_4) = (x_2, z_1 z_2 z_4) = (x_3, z_1 z_2 z_4) = 1
\]

and where

\[
\begin{align*}
\ell &:= (\ell_1, \ell_2, \ell_3), \quad d := (d_{12}, d_{13}, d_{21}, d_{23}, d_{31}, d_{32}), \\
b_1 &:= [e_1, d_{12}, d_{13}], \quad b_2 := [e_2, d_{21}, d_{23}], \quad b_3 := [e_3, d_{31}, d_{32}], \\
c_1 &:= [d_{21}, d_{31}, \ell_1, \ell_1], \quad c_2 := [d_{12}, d_{32}, \ell_1, \ell_2], \quad c_3 := [d_{13}, d_{23}, \ell_1, \ell_3], \quad c_4 := [e_1, e_2, e_3]
\end{align*}
\]

and, with a slight abuse of notation,

\[
\mu(e, d, \ell) := \mu(\ell_1) \mu(\ell_2) \mu(\ell_3) \prod_{1 \leq i < j \leq 3} \mu(d_{ij}).
\]

**Proof.** This is just an immediate application of Möbius’ inversion formula. \( \square \)

**Lemma 6.** With the notations of (6.1) and for real numbers \( u_1, u_2, u_3, w_1, w_2, w_3, w_4 \) satisfying

\[
\begin{align*}
&u_i, w_i + w_4 - 1 - \varepsilon \geq \kappa, \quad \forall i \in \{1, 2, 3\}; \quad w_4 \geq 0; \quad \kappa \geq 0; \\
u_i + w_j - \kappa > 1 + \varepsilon, \quad \forall i, j \in \{1, 2, 3\}, i \neq j; \quad w_i + w_j - \kappa > 1 + \varepsilon, \quad \forall i, j \in \{1, 2, 3\}, i < j;
\end{align*}
\]

we have

\[
\sum_{e, \ell, d \in \mathbb{N}^6} \max(b_1 c_1, b_2 c_2, b_3 c_3, b_4 c_4)^\kappa \ll 1.
\]
Proof. We have the formal Euler product formula
\begin{equation}
\sum_{\substack{e,\ell \in \mathbb{N}^6 \\
e\in \{0\}}} \frac{1}{b_1^{e_1} b_2^{e_2} b_3^{e_3} c_1^{e_4} c_2^{e_5} c_3^{e_6}} = \prod_p \left( \sum_{e',\ell' \in \mathbb{Z}_{\geq 0}^6} p^{-(b_1^{e_1} b_2^{e_2} b_3^{e_3} c_1^{e_4} c_2^{e_5} c_3^{e_6})} \right),
\end{equation}
where
\begin{equation}
b_1' = \max(e_1', d_1), b_2' = \max(e_2', d_2'), b_3' = \max(e_3', d_3), c_1' = \max(e_1', e_2', e_3'), c_2' = \max(d_1', d_2', \ell_1', \ell_2'), c_3' = \max(d_1', d_2', \ell_1', \ell_2').
\end{equation}
We have that the \(p\)-factor of the Euler product is
\begin{equation}
1 + O\left( \sum_{1 \leq i \leq 3} p^{-(u_i + w_i)} + \sum_{1 \leq i < j \leq 3} p^{-(u_i + w_j)} \right)
\end{equation}
and thus both sides of \(\text{6.4}\) converge whenever each of the exponents above are smaller than \(-1\).

As for \(\text{6.3}\), we notice that by symmetry it suffices to consider the contribution to the series coming from the terms with \(b_1 c_1 \geq b_2 c_2, b_3 c_3\). This is less or equal than the left hand side of \(\text{6.4}\) with \((u_1, w_1)\) replaced by \((u_1 - \kappa, w_1 - \kappa)\) and the lemma follows.

Lemma 7. With the notations of \(\text{6.1}\) and for \(a = (a_1, a_2, a_3) \in \mathbb{Z}_{\neq 0}^3\), let
\begin{equation}
\mathcal{G}_a^*: = \sum_{q \geq 1} \varphi(q) \sum_{\substack{a \in \mathbb{Z}_{\geq 3}^3 \\
ed \in \{0\}^6}} \mu(a, d, \ell) (a_1 b_1 c_1, q)(a_2 b_2 c_2, q)(a_3 b_3 c_3, q)
\end{equation}
Then \(\mathcal{G}_{(1, 1, 1)}^* = \mathcal{G}_2\) with \(\mathcal{G}_2\) as in Theorem 2.

Proof. With the same notations as in \(\text{6.5}\), we have that for \(a = 1\), the right hand side of \(\text{6.6}\) is equal to
\begin{equation}
\prod_p \left( \sum_{\substack{q \in \mathbb{Z}_{\geq 0}, \ell' \in \{0\}^6 \\
e, \ell' \in \{0\}^6}} (p - 1)^{\rho_q} \cdot \left(1 - 1\right)^{e_1 + e_2 + c_3 + d_1' + d_2' + d_3 + d_1 + d_2 + d_3 + \ell_1' + \ell_2'}
\end{equation}
where \(\rho_0 = 0\) and \(\rho_q' = 1\) if \(q' \geq 1\). As in lemma 2.7 of \(\text{8}\) we observe that the terms with \(q' \geq 2\) do not contribute. Indeed, if \(q' \geq 2\), then \(\min(q', b_1 + c_3) = b_1 + c_3\) so that the exponent of \(p\) above is \(2q' + c_3\) and so it does not depend on \(d_1'\). In particular the contributions of \(d_1' = 0\) and \(d_1' = 1\) cancel out. After restricting the sum over \(q'\) to \(q' \in \{0, 1\}\), we are left with performing a finite computation over the \(2^{13}\) possible values of the variables. With the help of a mathematical software we then obtain the claimed Euler product formula for \(\mathcal{G}_{(1, 1, 1)}^*\).

We are now ready to prove our Theorem 2.

Proof of Theorem 2 Let \(K^*_s(B)\) as in \(\text{5.3}\) but imposing also the coprimality conditions \(\text{5.2}\). In particular, by \(\text{2.2}\) we have
\begin{equation}
N_{\hat{W}_3, \hat{H}}(B) = K^*_{(1, 1, 1)}(B) + N'_{\hat{W}_3, \hat{H}}(B),
\end{equation}
where \(N'_{\hat{W}_3, \hat{H}}(B)\) counts the number of points in \(\hat{W}_3\) of height less than \(B\) which also satisfy \(x_1 x_2 x_3 = 0\). Now, for \(x_3 = 0\) (and thus \(y_3 = 1\)) then \(\text{1.1}\) reduces to \(\frac{x_1}{y_1} + \frac{x_2}{y_2} = 0\). Since we have \((x_1, y_1) = (x_2, y_2) = 1\), then \(x_1 = -x_2, y_1 = y_2\) and thus
\begin{equation}
N'_{\hat{W}_3, \hat{H}}(B) = 1 + 3 \sum_{x \in \mathbb{Z}, \nu \in \{0, 1\}} 1 = \frac{36}{\pi^2} B + O\left(B^{3/2} \log B\right).
\end{equation}
In particular, it suffices to prove an asymptotic formula with power saving error term for $K_{1,1,1}^*(B)$. Since it doesn’t introduce any difficulties, in the following we shall compute an asymptotic formula for $K_a^*(B)$ for all $a \in \mathbb{Z}_{>0}^3$.

Let $0 < \delta < \frac{1}{2}$. Using the same approach used for Proposition 1 and with the notations of Lemma 3 and of the proof of Proposition 1, we need to compute an asymptotic formula for

$$K_a^+(B) = \sum \frac{\mu(e, d, \ell)}{(2\pi i)^8} \int_{(c_1)} B^\frac{1}{4}(a_1 + a_2 + a_3 - \xi) \left( \frac{1}{c_1^4} \right)^{b_1 (a_1 + a_2 + a_3 - \xi) - \xi} \left( \frac{1}{c_2} \right)^{-\xi} \left( \frac{1}{c_3} \right)^{-\xi} \prod_{i \leq S_3} \frac{B}{|I_i|} \prod_{j \leq J} |x_{ij}| \prod_{j \leq J} z_j^{-1} \right),$$

With the notations of Lemma 3, we can rewrite this as

$$K_a^+(B) = \sum \frac{\mu(e, d, \ell)}{(2\pi i)^8} \int_{(c_1)} B^\frac{1}{4}(a_1 + a_2 + a_3 - \xi) \left( \frac{1}{c_1^4} \right)^{b_1 (a_1 + a_2 + a_3 - \xi) - \xi} \left( \frac{1}{c_2} \right)^{-\xi} \left( \frac{1}{c_3} \right)^{-\xi} \prod_{i \leq S_3} \frac{B}{|I_i|} \prod_{j \leq J} |x_{ij}| \prod_{j \leq J} (c_j z_j)^{-1},$$

where $a^* := (a_1^*, a_2^*, a_3^*) = (a_1 b_1 c_1, a_2 b_2 c_2, a_3 b_3 c_3)$ with $b_i, c_i$ as in (6.1). Thus, proceeding as in Proposition 1 and using the same notations and lines of integrations we find the following expression for $K_a^+(B)$

$$E_a^+(B) \ll \sum \frac{\mu(e, d, \ell)}{(2\pi i)^8} \int_{(c_1)} B^\frac{1}{4}(a_1 + a_2 + a_3 - \xi) \left( \frac{1}{c_1^4} \right)^{b_1 (a_1 + a_2 + a_3 - \xi) - \xi} \left( \frac{1}{c_2} \right)^{-\xi} \left( \frac{1}{c_3} \right)^{-\xi} \prod_{i \leq S_3} \frac{B}{|I_i|} \prod_{j \leq J} |x_{ij}| \prod_{j \leq J} (c_j z_j)^{-1}.$$

Notice that by (6.3) with $\kappa = 0$ the outer series converges absolutely. We keep following the same approach as the proof of Proposition 1 splitting $A_\ell$ into $M_a + \mathcal{E}_a$ and thus $K_a^+(B)$ into $M_a^+(B) + E_a^+(B)$. We can treat $E_a^+(B)$ as above with the only difference that in this case we move $c_3$ to $\frac{1}{2} - 2\gamma + \varepsilon$, where $\gamma := \frac{1}{391 - \sqrt{152737}}$ (this value is the smallest one can take under the condition that the inequalities (6.2) are satisfied). With this choice, (4.4) and (6.3) give the bound

$$E_a^+(B) \ll \sum \frac{\mu(e, d, \ell)}{(2\pi i)^8} \int_{(c_1)} B^\frac{1}{4}(a_1 + a_2 + a_3 - \xi) \left( \frac{1}{c_1^4} \right)^{b_1 (a_1 + a_2 + a_3 - \xi) - \xi} \left( \frac{1}{c_2} \right)^{-\xi} \left( \frac{1}{c_3} \right)^{-\xi} \prod_{i \leq S_3} \frac{B}{|I_i|} \prod_{j \leq J} |x_{ij}| \prod_{j \leq J} (c_j z_j)^{-1}.$$

where $A := \max_{1 \leq i \leq 3} |a_i|$. As for $M_a^+(B)$, we treat it exactly as in Proposition 1, splitting it into

$$M_a^+(B) = \sum \frac{\mu(e, d, \ell)}{(2\pi i)^8} \int_{(c_1)} \prod_{i \leq S_3} \frac{B}{|I_i|} \prod_{j \leq J} |x_{ij}| \prod_{j \leq J} (c_j z_j)^{-1}.$$

with $s := \frac{1}{3} - \frac{1}{3} \sum_{I \neq S_3} (3 - |I|) s_{I_1}$, $s_{123} := \frac{\xi}{3} - \frac{1}{3} \sum_{I \neq S_3} |I| s_{I_1}$, lines of integration $c_I = \frac{1}{2\pi i}$ for all $I \neq S_3, 0$. Using the notations of Lemma 3 and of the proof of Proposition 1, we need to compute an asymptotic formula for

$$M_a^+(B) = B P_\ell^*(\log B) + O_A \left( B^{\frac{27}{10} + 8\varepsilon} - 1 - \varepsilon + B^{1 + 5\varepsilon} \delta^{1/7} \right)$$

by (5.13) and (6.3). For $M_a^+(B)$ we find similarly as in the proof of Proposition 1
where \( P^*_a \) is a degree 3 polynomial with leading constant

\[
P^*_{a,3} := \sum_{e, f \in \mathbb{N}^3, d \in \mathbb{N}^6} \frac{\mu(e, f, d)}{(2\pi i)^6} \int_{(\gamma)} \frac{Q_{a^*,3}(\alpha, 0)}{\prod_{t \neq 0, S_3} d_{s_i}/s_i}
\]

and \( \alpha_2, \alpha_3 \) as in \([5, 21]\) and \( \alpha_1 = 2 - \alpha_2 - \alpha_3 \). Now,

\[
Q_{a^*,3}(\alpha, 0) = 2\pi^{\frac{5}{2}} \sum_{l=1}^{\infty} \left( a_1 b_1 c_1, l \right) \left( a_2 b_2 c_2, l \right) \left( a_3 b_3 c_3, l \right) \varphi(l) f^3 \prod_{t=1}^{3} \left( \frac{\Gamma(1 - \alpha)}{a_t^{1 - \alpha} \Gamma(\frac{\alpha}{3})} \right).
\]

and hence by the same computation as in Proposition \([1]\) we find \( P^*_{a,3} = \frac{1}{114} \mathcal{G}_a T_a \) with \( \mathcal{G}_a \) as in Lemma \([7]\).

Finally, we treat \( M^*_{a,2}(B) \) exactly as in Proposition \([1]\) and so, collecting the various asymptotics and bounds, we arrive to

\[
K^*_{a}(B) := BP^*_a(\log B) + W^*_a B + O_A \left( B^{1+5\gamma \xi^{1-\varepsilon}} + B^{1-2\gamma+13\varepsilon - \frac{56\gamma}{13} - 7\varepsilon} \right)
\]

for a certain \( W^*_a \in \mathbb{R} \). Choosing \( \delta = B^{-\frac{\gamma(2-2\gamma)}{4\gamma - 6\varepsilon}} \) we obtain

\[
K^*_{a}(B) := BP^*_a(\log B)^3 + W^*_a B + O_A \left( B^{1-\frac{2\gamma-27\varepsilon}{4\gamma - 6\varepsilon} + 13\varepsilon} \right)
\]

In particular, by \([6, 5]\), \([6, 8]\) and Lemma \([7]\) and recalling that \( \gamma = \frac{391 - \sqrt{325737}}{108} \) we obtain Theorem \([2]\) for all \( \xi \leq 1165 - 3\sqrt{152737} - 5264 = 0.00228169 \ldots \)

7. PROOF OF THEOREM \([1]\)

By \([2, 3]\) and renaming for simplicity \( z_0 = d_1, z_5 = d_2, z_3 = d_3 \) and \( z_4 \) by \( z_3 \) we have to count the solutions to

\[
x_1 d_1 + x_2 d_2 + x_3 d_3 = 0
\]

where \( x \in \mathbb{Z}^3 \neq 0, d, z \in \mathbb{N}^3 \) with \( x = (x_1, x_2, x_3), d = (d_1, d_2, d_3), z = (z_1, z_2, z_3) \) subject to the coprimality conditions

\[
\begin{align*}
(d_i, d_j) &= (z_i, z_j) = (d_k, z_k) = 1 & \forall i, j, k \in \{1, 2, 3\}, i \neq j, \\
(x_1, x_2, x_3) &= (x_i, x_j, z_k) = 1 & \forall i, j, k \text{ such that } \{i, j, k\} = \{1, 2, 3\},
\end{align*}
\]

and

\[
\max_{1 \leq i, j, k \leq 3} \left\{ |x_i z_i|^2 d_1 d_2 d_3 \frac{z_i}{d_j} \right\} \leq B.
\]

Let \( 0 < \delta < \frac{1}{2} \). This parametrization and \([2, 3]\) then imply that we just need to consider

\[
N^\pm_{\delta}(B) := 2 \sum_{x \in \mathbb{Z}_\neq 0^3} \prod_{1 \leq i, j \leq 3} P^\pm_\delta \left( (x_i z_i)^2 \frac{d_1 d_2 d_3 z_j}{d_j} B \right),
\]

where \( \sum' \) indicates the coprimality conditions \([7, 1]\), since for all \( \delta > 0 \) we have

\[
N^-_{\delta}(B) \leq N^-_{W, \tilde{H}}(B) \leq N^+_{\delta}(B).
\]

We shall prove

\[
N^\pm_{\delta}(B) = BP_1(\log B) + O \left( B^{1+\varepsilon \delta^{1-C\varepsilon}} + B^{1-K \delta^{1-C}} \right)
\]

where \( P_1 \) is a polynomial of degree 4 with leading coefficient \( \frac{\mathcal{G}_a T_a}{144} \) with the notations of Theorem \([1]\) and for some \( C, K > 0 \) and \( \varepsilon > 0 \) small enough, so that choosing \( \delta = B^{-K/(C+1)} \), we obtain Theorem \([4]\)
7.1. Initial manipulations. We write the $F^\pm_\delta$ in term of its Mellin transform using the variable $s_{ij}$ for the cut-off function corresponding to $(i,j)$ and choosing

$$c_{s_{ij}} = \frac{1}{9} + \varepsilon, \quad c_{s_{2j}} = \frac{1}{9} + 4\varepsilon, \quad c_{s_{1j}} = \frac{1}{9} + 6\varepsilon$$

as lines of integration for all $j \in \{1, 2, 3\}$. We obtain

$$N^\pm_\delta(B) = 2 \sum_{\substack{\alpha \in \mathbb{Z}_{\geq 0}^4, \delta \in \mathbb{Z}^3 \\ s_1 d_1 + s_2 d_2 + s_3 d_3 = 0}} \left( \frac{1}{(2\pi i)^9} \int \int \sum_{i,j} B^{\sum_{s_{ij}} s_{ij}} \frac{d_k}{d_k^2 \sum_{i,j \neq k} s_{ij}} 2^j s_{ij} \sum_{k \neq i,j} s_k \prod_{i,j} F^\pm_\delta(s_{ij}) \right)$$

$$= 2 \sum_{\substack{\alpha \in \mathbb{Z}_{\geq 0}^4, \delta \in \mathbb{Z}^3 \\ s_1 d_1 + s_2 d_2 + s_3 d_3 = 0}} \left( \frac{1}{(2\pi i)^9} \int \int \sum_{i,j} B^{s^*} \frac{d_k}{d_k^2 \sum_{i,j \neq k} s_{ij}} \sum_{k} F^\pm_\delta(s_{ij}) \right)$$

where

$$\alpha_k := \frac{1}{2} \sum_{1 \leq i,j \leq 3} s_{ij} + \sum_{1 \leq j \leq 3} s_{kj} - \frac{1}{2} \sum_{1 \leq i \leq 3} s_{ik}, \quad \xi_k := \frac{1}{2} \sum_{1 \leq i,j \leq 3} s_{ij} - \sum_{1 \leq j \leq 3} s_{kj}, \quad \forall k \in \{1, 2, 3\}$$

$$s^* := \sum_{1 \leq i,j \leq 3} s_{ij}$$

so that

$$\alpha_k - \xi_k = 2 \sum_{1 \leq i,j \leq 3} s_{kj}, \quad \alpha_k + \xi_k = \sum_{1 \leq i,j \leq 3} s_{ij}.$$

Note that we have

$$(7.4) \quad \xi_1 + \xi_2 + \xi_3 = 0, \quad \alpha_1 + \alpha_2 + \alpha_3 = 2s^*$$

and that, like in the proof of Theorem 2, we are neglecting the dependencies of these notations on variables $s_{ij}$ in order to simplify the exposition. Also, notice that with the above lines of integration we have

$$\Re(\xi_1) = 8\varepsilon, \quad \Re(\xi_2) = -\varepsilon, \quad \Re(\xi_3) = -7\varepsilon, \quad \Re(s^*) = 1 + 33\varepsilon$$

$$(7.5) \quad \Re(\alpha_1) = \frac{2}{3} + 14\varepsilon, \quad \Re(\alpha_2) = \frac{2}{3} + 23\varepsilon, \quad \Re(\alpha_3) = \frac{2}{3} + 29\varepsilon$$

so that in particular the above series are absolutely convergent by Lemma 2.

We make a change of variables, discarding the variables $s_{11}, s_{22}, s_{13}, s_{23}, s_{33}$, and introducing the variables $\alpha_1, \alpha_2, \xi_1, \xi_2$ and $s^*$. The inverse transformations are

$$s_{11} = s^* - \alpha_1 - \xi_1 - s_{21} - s_{31}, \quad s_{22} = s^* - \alpha_2 - \xi_2 - s_{12} - s_{32},$$

$$(7.6) \quad s_{13} = -s^* + \frac{3}{2} \alpha_1 + \frac{1}{2} \xi_1 - s_{12} + s_{21} + s_{31}, \quad s_{23} = -s^* + \frac{3}{2} \alpha_2 + \frac{1}{2} \xi_2 + s_{12} - s_{21} + s_{32},$$

$$s_{33} = s^* + \frac{1}{2} (\alpha_1 + \alpha_2 - \xi_1 - \xi_2) - s_{31} - s_{32}$$

and the Jacobian is equal to 1. In the following, to simplify the exposition, we shall keep using also the older variables (as well as $\xi_3$ and $\alpha_3$ given by (7.4), treating them as function of the new ones.
7.2. Resolving the coprimality conditions. For $\Re(\alpha_k \pm \xi_k) > \frac{2}{3}$ and $\Re(s^* - 2\xi_k) > 1$, using M"obius inversion formula to remove the coprimality conditions (7.1) (this is lemma 2.1 of [8]) we obtain

$$
\sum' \prod_{k=1}^{3} \frac{1}{x_k^{\alpha_k - \xi_k + \epsilon \delta_k + \xi_k + s^* - 2\xi_k}}
$$

(7.7)

$$
= \sum_{b,e,f,g \in \mathbb{N}^3} \sum_{\tau \in \mathbb{N}^3} \mu(h) \prod_{k=1}^{3} \frac{\mu(b_k) \mu(c_k) \mu(f_k) \mu(g_k)}{\prod_{k=1}^{3} (r_{1,k} x_k)^{\alpha_k - \xi_k + \epsilon \delta_k + \xi_k + s^* - 2\xi_k}}
$$

= \sum_{b,e,f,g \in \mathbb{N}^3} \mu(h) \left( \prod_{k=1}^{3} \frac{\mu(b_k) \mu(c_k) \mu(f_k) \mu(g_k)}{r_{1,k}^{\alpha_k - \xi_k + \epsilon \delta_k + \xi_k + s^* - 2\xi_k}} \right) A_r(\alpha - \xi, \alpha + \xi),
$$

with the notation of Lemma 2 and where for $\{i,j,k\} = \{1,2,3\}$ we defined

$$
r_{1,k} := [g_i, g_j, h], \quad r_{2,k} := [b_i, b_j, f_k], \quad r_{3,k} := [c_i, c_j, f_k, g_k], \quad r_k := r_{1,k} r_{2,k}.
$$

For future use we also observe that for $\sigma > \frac{1}{2} + \varepsilon$, with $\varepsilon > 0$, we have

$$
\sum_{b,e,f,g \in \mathbb{N}^3} \prod_{k=1}^{3} \frac{1}{r_{1,k} r_{2,k} r_{3,k}} = \prod_{p} \left( 1 + O(p^{-2\sigma}) \right) \ll 1,
$$

(7.9)

where, in the sum over $k$ in the first line, $i,j$ are such that $\{i,j,k\} = \{1,2,3\}$.

Now, by (7.7), we have

$$
N_{s^*}^{\pm}(B) = 2 \sum_{b,e,f,g \in \mathbb{N}^3} \mu(h) \int \left( \cdots \right) B^{s^*} \left( \prod_{k=1}^{3} \frac{\mu(b_k) \mu(c_k) \mu(f_k) \mu(g_k)}{r_{1,k}^{\alpha_k - \xi_k + \epsilon \delta_k + \xi_k + s^* - 2\xi_k}} \right)
$$

$$
\times A_r(\alpha - \xi, \alpha + \xi) \left( \prod_{i,j} F_{s_{ij}}^\pm(s_{ij}) \right) d(\cdots),
$$

where, here and below, we indicate by $\int \left( \cdots \right) d(\cdots)$ an integral with respect to the variables $s^*, \alpha_1, \alpha_2, \delta_1, \delta_2$ and $s_{12}, s_{21}, s_{31}, s_{32}$, along the lines of integration previously indicated, with the exclusion of the variables which have been eliminated by the computation of a residue.

7.3. Applying Lemma 2. We write $A_r(\alpha - \xi, \alpha + \xi)$ as $M_r(\alpha - \xi, \alpha + \xi) + E_r(\alpha - \xi, \alpha + \xi)$ and we split accordingly $N_{s^*}^{\pm}(B)$ into

$$
N_{s^*}^{\pm}(B) = M_{s^*}^{\pm}(B) + E_{s^*}^{\pm}(B).
$$

(7.10)

Differently from the case of Theorem 2 here $E_{s^*}^{\pm}(B)$ also contributes to a main term, of size $B$, which can be extracted as follow.

We move the lines of integration $c_{\xi_1}$, $c_{\xi_2}$ and $c_{s^*}$ in the integrals defining $E_{s^*}^{\pm}(B)$ to $c_{\xi_1} = 2K$, $c_{\xi_2} = -K$ and $c_{s^*} = 1 - K$ for some fixed real number $K > 0$ small enough, passing through the simple pole of the integrand at $s^* = 1 + 2\xi_1$. If $K$ is sufficiently small then we don’t pass through any other pole and we stay inside the region (4.3) where $E_r$ is holomorphic and where the sums are absolutely convergent. For the integral on the new lines of integration we use (4.4) and a trivial bound for $\zeta$ and
we obtain that, for $K$ small enough, the integral is bounded by

$$
\ll B^{1-K} \sum_{b, e_1, e_2 \in \mathbb{N}} \int_{(\cdots)} \left( \prod_{k=1}^{3} \frac{(r_k(\sqrt{s}) + |\xi_k|)(c_{e_1} + |\xi_k|)^{C_1 K}}{(r_1, r_2, r_3, k)^{\frac{3}{2} - K}} \right) \left| \prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij}) \right| d(\cdots)
$$

$$
\ll B^{1-K} \delta^{-C_2 K},
$$

where the second line is obtained as for (5.10) using (4.6) and (7.9), after reintroducing the original variables $s_{ij}$. Also, we remind that, here and below, $C_1, C_2, C_3, \ldots$ will indicate fixed positive real numbers.

Collecting the contribution of the residue we obtain

$$
E^{\pm}_{\delta}(B) = \frac{B}{6} \sum_{b, e_1, e_2 \in \mathbb{N}} \frac{\mu(h)}{(2\pi i)^6} \int_{(\cdots)} \left( \prod_{k=1}^{3} \frac{\mu(b_k)\mu(c_{e_1})\mu(f_k)\mu(g_k)}{r_k^{\alpha_k,\alpha_k,\alpha_k}} \right) \zeta(1+2\xi_1 - 2\xi_2) \zeta(1+4\xi_1 + 2\xi_2)
$$

$$
\times \xi_{\epsilon}(\alpha - \xi, \alpha + \xi) \left( \prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij}) \right) d(\cdots) + O(B^{1-K} \delta^{-C_2 K}),
$$

since $\xi_3 = -\xi_1 - \xi_2$ and with the notations (7.6). We then move the line of integration $c_{\xi_1} = c_{\xi_2} = -K/2$ passing through the pole at $\xi_1 = -\xi_2/2$. The integral on the new lines of integration can be bounded as above, whereas in the integral coming from the contribution of the residue, we move $c_{\xi_2}$ to $c_{\xi_2} = K$ passing through a simple pole at $\xi_2 = 0$ (in which case $\xi_3 = 0$). Bounding once again the contribution of the integral as above we arrive to

$$
E^{\pm}_{\delta}(B) = \frac{B}{6} \sum_{b, e_1, e_2 \in \mathbb{N}} \frac{\mu(h)}{(2\pi i)^6} \int_{(\cdots)} \left( \prod_{k=1}^{3} \frac{\mu(b_k)\mu(c_{e_1})\mu(f_k)\mu(g_k)}{r_k^{\alpha_k,\alpha_k,\alpha_k}} \right) \xi_{\epsilon}(\alpha - \xi, \alpha + \xi) \left( \prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij}) \right) d(\cdots)
$$

$$
+ O(B^{1-K} \delta^{-C_3 K}).
$$

The product $\prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij})$ can now be replaced by $\prod_{i,j} \frac{1}{s_{ij}}$ at a cost of an error which is $O(B^{3/4-C_5 \epsilon})$. Indeed, by (4.4) and (7.9) we have

$$
\sum_{b, e_1, e_2 \in \mathbb{N}} \frac{\mu(h)}{(2\pi i)^6} \int_{(\cdots)} \left( \prod_{k=1}^{3} \frac{\mu(b_k)\mu(c_{e_1})\mu(f_k)\mu(g_k)}{r_k^{\alpha_k,\alpha_k,\alpha_k}} \right) \xi_{\epsilon}(\alpha - \xi, \alpha + \xi) \left( \prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij}) - \frac{1}{s_{ij}} \right) d(\cdots)
$$

$$
\ll \int_{(\cdots)} \left( \prod_{i,j} \left| \hat{F}_{\delta}^{\pm}(s_{ij}) - \frac{1}{s_{ij}} \right|^{C_5 \epsilon} \right) d(\cdots) \ll \delta^{1-C_5 \epsilon},
$$

by proceeding as in (5.10) after reintroducing six of the variables $s_{ij}$ (with the remaining three variables kept as functions of those), since we now have the extra relation $\sum_{1 \leq i,j \leq 3} s_{ij} = s^* = 1$. Collecting the above computations, we then get

$$
(7.11) \quad E^{\pm}_{\delta}(B) = BP_0 + O(B^{3/4-C_5 \epsilon} + B^{1-K} \delta^{-C_5 K})
$$

for some $P_0 \in \mathbb{R}$.

We now move to the analysis of $M^{\pm}_{\delta}(B)$. Following the definition of $M_{\epsilon}$, we split $M^{\pm}_{\delta}(B)$ in the following way

$$
(7.12) \quad M^{\pm}_{\delta_{\epsilon}}(B) = \sum_{\epsilon \in \{\pm1\}^3} M_{\delta_{\epsilon}}^{\pm}(B),
$$

where the sum is over $\epsilon = (\epsilon_1, \epsilon_2, \epsilon_3) \in \{\pm1\}^3$ and

$$
(7.13) \quad M_{\delta_{\epsilon}}^{\pm}(B) := \frac{2}{(2\pi i)^9} \int_{(\cdots)} B^{s^*} \prod_{k} \frac{\zeta(s^* - 2\xi_k)(1 + 2\epsilon_k \xi_k)}{2s^* - \epsilon_1 \xi_1 - \epsilon_2 \xi_2 - \epsilon_3 \xi_3 - 2} Q_{\epsilon}(\alpha, \xi) \left( \prod_{i,j} \hat{F}_{\delta}^{\pm}(s_{ij}) \right) d(\cdots)
$$
with lines of integration as given in Section 7.1 (in particular (7.9) is satisfied) and where
\[ Q_\epsilon(\alpha, \xi) := \sum_{b, c, f, g \in \mathbb{G}^{3,3}} \mu(h) \left( \prod_{k=1}^{3} \frac{\mu(b_k) \mu(c_k) \mu(f_k) \mu(g_k)}{\mu(r_{1,k}) \alpha_{1,k} \alpha_{2,k} \alpha_{3,k} \epsilon_{s}^{r_{3,k}}} \right) \left( r_{1, \ell} \right)^{1+2\epsilon_{r_{1} \xi_{1}}(r_{2, \ell})} \left( r_{3, \ell} \right)^{1+2\epsilon_{r_{3} \xi_{3}}} \frac{\varphi(\ell)}{\beta^{3+2\epsilon_{r_{1} \xi_{1}}+2\epsilon_{r_{3} \xi_{3}}}} \]
\[ \times 2\pi i \prod_{i, \xi_{i} \in \mathbb{G}^{3,3}} \frac{\Gamma(-\alpha_{i} \xi_{i} + \frac{1}{2} \epsilon_{s} \xi_{i} - 1) \Gamma(1 + \frac{1}{2} \epsilon_{s} \xi_{i})}{\Gamma(1 + \alpha_{i} \xi_{i} - 1) \Gamma(1 + \frac{1}{2} \epsilon_{s} \xi_{i})} \]
where we recall that \( 2s^* = \alpha_1 + \alpha_2 + \alpha_3 \) and the notations (7.6). Notice that by (7.9) and (5.14) we have that \( Q_\epsilon(\alpha, \xi) \) is holomorphic and bounded for \[ |\Re(s^* - 1)|, |\Re(\xi_{i})|, |\Re(\alpha_{i} - \frac{3}{2})| < 20K, \]
with \( K \) small enough.

Now, we move the lines of integration \( c_{s^*}, c_{\xi_1}, c_{\xi_2} \) in (7.13) to \( c_{s^*} = 1 - K, c_{\xi_1} = 16K, c_{\xi_2} = -14K \) (so that on the new lines of integration \( \Re(\xi_{i}) = -2K \) since \( \xi_{1} + \xi_{2} + \xi_{3} = 0 \)) passing through simple poles at \( s^* = 1 + 2\xi_{1} \) and, if \( \epsilon \notin \{(-1, 1, 1), (-1, -1, 1), (-1, 1, -1)\} \), at \( s^* = 1 + \frac{1}{2}(\epsilon_{1} \xi_{1} + 2\epsilon_{2} \xi_{2} + 3\epsilon_{3} \xi_{3}) \). Indeed, the denominator has positive real part on the original lines of integrations whereas on the new lines of integrals it has real part equal to \( 2(-K - 8\epsilon_{1} K + 7\epsilon_{2} K + 3\epsilon_{3} K) \) which is negative if and only if \( \epsilon_{1} = 1 \) or \( \epsilon_{1} = \epsilon_{2} = \epsilon_{3} = -1 \). Also note that we stay on the same side of the poles of the other \( \xi \) factors. Alluding to (6.16), a trivial bound for \( \zeta \) and the fact that \( Q_\epsilon \) is bounded, we can use the same argument used several times in Sections 6.6 in order to bound trivially the contribution of the integral on the new lines of integration obtaining that its contribution is \( O(B^{1-K/2-\delta-C_{\epsilon}}) \).

It follows that
\[ M_{\epsilon}^{\pm}(B) = M_{\epsilon,1}^{\pm}(B) + M_{\epsilon,2}^{\pm}(B), \]
where \( M_{\epsilon,1}^{\pm} \) denotes the contribution of the pole at \( s^* = 1 + 2\xi_{1} \) and \( M_{\epsilon,2}^{\pm}(B) \) is the contribution of the pole at \( s^* = 1 + \frac{1}{2}(\epsilon_{1} \xi_{1} + 2\epsilon_{2} \xi_{2} + 3\epsilon_{3} \xi_{3}) \) if \( \epsilon \notin \{(-1, 1, 1), (-1, -1, 1), (-1, 1, -1)\} \) and \( M_{\epsilon,2}^{\pm}(B) := 0 \) otherwise.

7.4. The pole at \( s^* = 1 + 2\xi_{1} \) when \( \epsilon \neq (1, -1, 1) \). Using the fact that \( \xi_{3} = -\xi_{1} - \xi_{2} \) we have
\[ M_{\epsilon,1}^{\pm}(B) = \frac{2}{(2\pi i)^{8}} \int_{\cdots} B^{1+2\xi_{1}} \prod_{k \neq 1} \zeta(1 + 2\xi_{1} - 2\xi_{k}) \prod_{k=1}^{3} \zeta(1 + 2\epsilon_{r_{i} \xi_{i}}) \]
\[ \times Q_\epsilon(\alpha, \xi) \left( \prod_{i,j} F_{\delta}(s_{ij}) \right) \text{d}(\cdots) \]
\[ = \frac{2}{(2\pi i)^{8}} \int_{\cdots} B^{1+2\xi_{1}} \frac{\zeta(1 + 2\xi_{1} \xi_{1}) \zeta(1 + 2\xi_{1} - 2\xi_{2}) \zeta(1 + 2\epsilon_{r_{3} \xi_{3}})}{\zeta(1 + 4\xi_{1} + 2\xi_{2}) \zeta(1 - 2\epsilon_{r_{3} \xi_{3}})} \]
\[ \times Q_\epsilon(\alpha, \xi) \left( \prod_{i,j} F_{\delta}(s_{ij}) \right) \text{d}(\cdots), \]
with \( c_{\xi_{1}} = 8\epsilon \) and \( c_{\xi_{2}} = -\epsilon \). Notice that for \( \epsilon = (1, -1, 1) \) one has a double pole when \( 4\epsilon_{1} + 2\epsilon_{2} = 0 \) which causes some (mostly notational) issues when moving the lines of integration as we shall do throughout this section. For this reason, we prefer to defer to the next section the treatment of this term.

Next, we move the lines of integration \( c_{\xi_{1}} \) and \( c_{\xi_{2}} \) to \( c_{\xi_{1}} = -K \) and \( c_{\xi_{2}} = -4K \) passing through several poles. As before, the integral on the new lines of integration is \( O(B^{1-K/2-\delta-C_{\epsilon}}) \). The poles we encounter are the following:
(a) a pole at \( \xi_{1} = 0 \) which is simple if \( \epsilon_{2} \neq \epsilon_{3} \) and is double if \( \epsilon_{2} = \epsilon_{3} \);
(b) a simple pole at \( \xi_{1} = -\frac{1}{2} \xi_{2} \);
(c) a simple pole at \( \xi_{1} = -\xi_{2} \);
We show this we first observe that, by the convexity bound (5.1.4), on the lines of integration

\[ \zeta(1 + 4\xi_1 + 2\xi_2) \zeta(1 + 3(\xi_1 + \xi_2)) Q_\alpha(\alpha, \xi) \left( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \right) d(\cdot) \]

where we can assume that the line of integration \( c_{\xi_2} \) is at \( c_{\xi_2} = -\varepsilon \). The next step is to observe that we can replace \( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \) by \( \prod_{i,j} \frac{1}{s_{ij}} \) at a cost of an error which is

\[ O(B^{1+\varepsilon} \delta^{-1-C_0\varepsilon}) \]  

To show this we first observe that, by the convexity bound (5.1.4), on the lines of integration the integrand is

\[ \ll \log B (1 + |\xi_1| + |\xi_2|)^{10^6} \prod_{i,j} |\tilde{F}^{\pm}_{\delta}(s_{ij})| \ll \log B \prod_{i,j} |\tilde{F}^{\pm}_{\delta}(s_{ij})|(1 + |s_{ij}|)^{C_{11}\varepsilon}. \]

We go back to using the \( s_{ij} \) as variables (excluding for example the variable \( s_{11} \) because we have a variable less) and observe we have \( s^* = \sum_{1\leq i,j\leq 3} s_{ij} = 1 + 2\xi_1 = 1 + O(\varepsilon) \) and thus \( s_{11} = 1 - \sum_{(i,j)\neq(1,1)} s_{ij} + O(\varepsilon) \). Thus, proceeding as for (5.16) we can replace \( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \) by \( \prod_{i,j} \frac{1}{s_{ij}} \) at a cost of an error which is bounded by (7.15). In the end, we find that the contribution of the pole at \( \xi_1 = 0 \) is

\[ BP_{\varepsilon,1.1}(\log B) + O(B^{1+\varepsilon} \delta^{-1-C_0\varepsilon} + B^{1-K \delta^{-C_0\varepsilon}}) \]

where \( P_{\varepsilon,1.1} \) is a polynomial of degree 0 or 1 (not depending on the choice for \( \delta \) and \( \pm \) in \( N^+_\delta(B) \)) obtained by evaluating the above integral with the \( \prod_{i,j} \frac{1}{s_{ij}} \) instead of \( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \).

(b) The contribution of the pole at \( \xi_1 = -\frac{1}{2} \xi_2 \) is

\[ \frac{-1}{(2\pi i)^7} \int_{(\cdot)} B^{-\varepsilon_2} \zeta(1 - \varepsilon_1 \xi_2) \zeta(1 - 3\xi_2) \zeta(1 + 2\xi_2) \zeta(1 - \varepsilon_3 \xi_2) \frac{(4 - \varepsilon_1 + 2\xi_2 - \varepsilon_3)_{\xi_2}}{(4 - \varepsilon_1 + 2\xi_2 - \varepsilon_3)_{\xi_2}} Q_\alpha(\alpha, \xi) \left( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \right) d(\cdot). \]

We move the line of integration \( c_{\xi_2} \) to \( c_{\xi_2} = K \) passing through a pole at \( \delta_2 = 0 \). The contribution of the integral on the new lines of integration is \( O\left( B^{1-K \delta^{-C_{12}\varepsilon}} \right) \). For the contribution of the residue, we follow the same approach as above writing it as a small circle integral and observing that since again \( s^* = \sum_{1\leq i,j\leq 3} s_{ij} = 1 + 2\xi_1 = 1 - \xi_2 = 1 + O(\varepsilon) \) we can replace \( \prod_{i,j} \tilde{F}^{\pm}_{\delta}(s_{ij}) \) by \( \prod_{i,j} \frac{1}{s_{ij}} \) at the cost of an error which is \( O\left( B^{1+\varepsilon} \delta^{-1-C_{12}\varepsilon} \right) \). Then, computing the integral we find that the contribution to (7.14) from the pole at \( \xi_1 = \frac{1}{2} \xi_2 \) is

\[ BP_{\varepsilon,1.2}(\log B) + O\left( B^{1+\varepsilon} \delta^{-1-C_{12}\varepsilon} + B^{1-K \delta^{-C_{12}\varepsilon}} \right) \]

where \( P_{\varepsilon,1.2} \) is a polynomial of degree 4 of leading coefficient

\[ -\frac{\epsilon_1 \epsilon_2 \epsilon_3}{2 \cdot 3 \cdot (4 - \epsilon_1 + 2\epsilon_2 - \epsilon_3)} J, \]

where

\[ J := \frac{1}{4!} \frac{1}{(2\pi i)^6} \int_{(\cdot)} Q_\alpha(\alpha, 0) \left( \prod_{i,j} \frac{1}{s_{ij}} \right) d(\cdot). \]

It is noteworthy that, since \( \xi = 0 \), \( J \) does not depend on \( \varepsilon \). Moreover, we will see below with (7.17) that \( J \neq 0 \).
(c) The contribution of the pole at $\xi_1 = -\xi_2$ is
\[
\frac{\epsilon_3}{(2\pi i)^7} \int_{(\cdots)} B^{1-2\xi_2} \zeta(1-2\xi_2)\zeta(1-4\xi_2)\zeta(1-2\xi_2)\zeta(1-2\xi_2) \frac{Q_\epsilon(\alpha, (-\xi_2, \xi_2, 0))\left(\prod_{i,j} \hat{F}_s^\pm(s_{ij})\right)}{(4-\epsilon_1 + \epsilon_2)\xi_2} d(\cdots)
\]
and proceeding as above we have that this is
\[
BP_{\epsilon,1,3}(\log B) + O\left(B^{1+\epsilon}\delta^{1-C_{1s}\epsilon} + B^{1-K}\delta^{1-C_{19}}\right)
\]
where $P_{\epsilon,1,3}$ is a polynomial of degree 4 of leading coefficient
\[
\frac{\epsilon_1\epsilon_2\epsilon_3}{2 \cdot (4-\epsilon_1 + \epsilon_2) J},
\]
with the notation (7.16).

(d) The contribution of the pole at $\xi_1 = -\frac{1}{3}\xi_2$ with $\epsilon = (-1,-1,1)$ is
\[
\frac{1}{3} \frac{1}{(2\pi i)^7} \int_{(\cdots)} B^{1-\frac{2}{3}\xi_2} \zeta(1+\frac{2}{3}\xi_2)\zeta(1-\frac{8}{3}\xi_2)\zeta(1-2\xi_2) \times \zeta(1+\frac{2}{3}\xi_2)\zeta(1-\frac{4}{3}\xi_2)Q_\epsilon(\alpha, \xi)\left(\prod_{i,j} \hat{F}_s^\pm(s_{ij})\right) d(\cdots)
\]
and, proceeding as above, we have that this is
\[
BP_{\epsilon,1,4}(\log B) + O\left(B^{1+\epsilon}\delta^{1-C_{1s}\epsilon} + B^{1-K}\delta^{1-C_{17}}\right)
\]
where $P_{\epsilon,1,4}$ is a polynomial of degree 4 of leading coefficient
\[
\frac{1}{2^4 \cdot 3 J}.
\]

Regrouping the above four contributions, we obtain that for $\epsilon \neq (1,-1,1)$ we have
\[
M_{\alpha,\epsilon,1}^\pm(B) = BP_{\epsilon,1}(\log B) + O\left(B^{1+\epsilon}\delta^{1-C_{1s}\epsilon} + B^{1-K}\delta^{1-C_{19}}\right)
\]
where $P_{\epsilon,1}$ is a degree 4 polynomial with leading coefficient
\[
J \times \begin{cases} 
\frac{-\epsilon_1\epsilon_2\epsilon_3}{2 \cdot 3 \cdot (4-\epsilon_1 + 2\epsilon_2 - \epsilon_3)} + \frac{\epsilon_1\epsilon_2\epsilon_3}{2 \cdot (4-\epsilon_1 + \epsilon_2)} & \text{if } \epsilon \neq (-1,-1,1), (1,-1,1) \\
\frac{1}{2^4} & \text{if } \epsilon = (-1,-1,1),
\end{cases}
\]
with the notation (7.16).

7.5. **The pole at $s^* = 1 + 2\xi_1$ for $\epsilon = (1,-1,1)$.** For brevity, in this section we write $\epsilon^* := (1,-1,1)$.

We have
\[
M_{\epsilon^*,1}^\pm(B) = \frac{2}{(2\pi i)^8} \int_{(\cdots)} B^{1+2\xi_1} \zeta(1+2\xi_1)\zeta(1+2\xi_1-2\xi_2)\zeta(1-2\xi_2) \times \zeta(1+4\xi_1+2\xi_2)\zeta(1-2(\xi_1+\xi_2))Q_{\epsilon^*}(\alpha, \xi)\left(\prod_{i,j} \hat{F}_s^\pm(s_{ij})\right) d(\cdots).
\]

Here, we move $c_{\xi_1}$ to $c_{\xi_2} = 2K$, passing through simple poles at $\xi_2 = 0$ and $\xi_2 = \xi_1$. For the integral on the new lines of integration, we move $c_{\xi_1}$ to $c_{\xi_1} = -K/2$ passing through a pole at $\xi_1 = 0$. If $K$ is sufficiently small, the integral on these new lines of integration can then be estimated trivially by $O\left(B^{1-K}\delta^{1-C_{20}}\right)$. Thus, overall we shall compute the following residues arising for the following poles
(a) a simple pole at $\xi_2 = 0$
(b) a simple pole $\xi_2 = \xi_1$;
(c) a simple pole at $\delta_1 = 0$ (with $c_{\xi_2} > 0$).
(a) The contribution of the residue at $\xi_2 = 0$ is
\[
\frac{1}{(2\pi i)^2} \int_{(\ldots)} B^{1+2\xi_2} \frac{\zeta(1+2\xi_1)^2 \zeta(1+4\xi_1) \zeta(1-2\xi_1)}{4\xi_1} Q_{c,\xi}(\alpha, \xi) \left( \prod_{i,j} \tilde{F}_{\delta}(s_{ij}) \right) d(\ldots)
\]
and, as in the previous section, one sees that this is
\[
BP_{c,1,4}(\log B) + O\left(B^{1+\varepsilon \delta^{1-C_{21}\varepsilon}} + B^{1-K \delta-C_{22}}\right)
\]
with $P_{c,4,1}$ of degree 4 with leading coefficient
\[-\frac{1}{2^4} \mathcal{J},\]
with the notation (7.16).

(b) The contribution of the residue at $\xi_1 = 0$ is
\[
\frac{1}{(2\pi i)^2} \int_{(\ldots)} B^{1+2\xi_2} \frac{\zeta(1+2\xi_1)^3 \zeta(1+2\xi_2) \zeta(1+4\xi_1) \zeta(1-2\xi_1)}{6\xi_1} Q_{c,\xi}(\alpha, \xi) \left( \prod_{i,j} \tilde{F}_{\delta}(s_{ij}) \right) d(\ldots)
\]
\[= BP_{c,1,2}(\log B) + O\left(B^{1+\varepsilon \delta^{1-C_{23}\varepsilon}} + B^{1-K \delta-C_{24}}\right)
\]
with $P_{c,1,2}$ of degree 4 with leading coefficient
\[-\frac{1}{2^4} \cdot 3^2 \mathcal{J}.
\]

(c) The contribution of the residue at $\xi_1 = 0$ is
\[
\frac{1}{(2\pi i)^2} \int_{(\ldots)} B \frac{\zeta(1-2\xi_2)^3 \zeta(1+2\xi_2)}{2\xi_2} Q_{c,\xi}(\alpha, \xi) \left( \prod_{i,j} \tilde{F}_{\delta}(s_{ij}) \right) d(\ldots)
\]
\[= P_{c,1,3} B + O\left(B^{1+\varepsilon \delta^{1-C_{25}\varepsilon}} + B^{1-K \delta-C_{26}}\right)
\]
with $P_{c,1,3} \in \mathbb{R}$.

Collecting the various terms, we then find that
\[
M_{c,1}(B) = BP_{c,1}(\log B) + O\left(B^{1+\varepsilon \delta^{1-C_{27}\varepsilon}} + B^{1-K \delta-C_{28}}\right)
\]
where $P_{c,1}$ is a polynomial of degree 4 with leading coefficient
\[-\frac{7}{2^4 \cdot 3^2} \mathcal{J}.
\]

7.6. **The pole at** $s^* = 1 + \frac{1}{2}(\varepsilon_1 \xi_1 + \varepsilon_2 \xi_2 + \varepsilon_3 \xi_3)$. Recall that $M_{c,2}(B) := 0$ if $\varepsilon = (-1,1,1), (-1,-1,1), (-1,1,-1)$. In all other cases we have
\[
M_{c,2}(B) = \frac{1}{(2\pi i)^8} \int_{(\ldots)} B^{1+\frac{1}{2}(\varepsilon_1 \xi_1 + \varepsilon_2 \xi_2 + \varepsilon_3 \xi_3)} \prod_k \zeta \left(1 + \frac{1}{2}(\varepsilon_1 \xi_1 + \varepsilon_2 \xi_2 + \varepsilon_3 \xi_3) - 2\xi_k \right) \zeta(1 + 2\varepsilon_k \xi_k)
\]
\[\times Q_{c}(\alpha, \xi) \left( \prod_{i,j} \tilde{F}_{\delta}(s_{ij}) \right) d(\ldots).
\]
If $\varepsilon_1 = \varepsilon_2 = \varepsilon_3$, then the exponent of $B$ is 1. In particular, since in this case we have the relation $s^* = \sum_{i,j} s_{ij} = 1$ because $\xi_1 + \xi_2 + \xi_3 = 0$, we can replace $\prod_{i,j} \tilde{F}_{\delta}(s_{ij})$ by $\prod_{i,j} s_{ij}^{-1}$ at a cost of an error which is $O(B^{1+\varepsilon \delta^{1-C_{25}\varepsilon}})$ like in Section 7.3. Thus, for $\varepsilon = (1,1,1), (-1,-1,-1)$ we have
\[
M_{c,2}(B) = P_{c,2,1} B + O\left(B^{1+\varepsilon \delta^{1-C_{26}\varepsilon}}\right)
\]
for some $P_{c,2,1} \in \mathbb{R}$.  

THE MANIN-PEYRE CONJECTURE FOR $x_1y_2y_3 + x_2y_1y_3 + x_3y_1y_2 = 0$
Therefore, we are left with considering the cases where \( \epsilon_r = -\epsilon_{k_1} = -\epsilon_{k_2} \) with \( \{r, k_1, k_2\} = \{1, 2, 3\} \) and \( k_1 < k_2 \). Notice in particular that since \( \xi_1 + \xi_2 + \xi_3 = 0 \), then we have \( \epsilon_1\xi_1 + \epsilon_2\xi_2 + \epsilon_3\xi_3 = 2\epsilon_r\xi_r \).

Thus,

\[
M_{\epsilon,2^\pm(B)} = \frac{1}{(2\pi i)^n} \int_{\cdot} B^{1+\epsilon_r\xi_r} \zeta(1 + (\epsilon_r - 2)\xi_r)\zeta(1 + \epsilon_r\xi_r - 2\epsilon_{k_1})\zeta(1 + 2\epsilon_{k_2}\xi_{k_1})\delta(\xi_r - \xi_r - 2\xi_{k_1} + 2\epsilon_{k_2}\xi_{k_1}) \\
\times \zeta(1 + (\epsilon_r + 2)\xi_r + 2\xi_{k_1})\zeta(1 - 2\epsilon_{k_2}(\xi_r + \xi_{k_1}))Q_\epsilon(\alpha, \xi)\left(\prod_{i,j} F_{1/\delta}(s_{ij})\right) d(\cdot).
\]

Notice that we made a change of variables (of jacobian \( \pm 1 \), since \( \xi_1 + \xi_2 + \xi_3 = 0 \)) using \( \xi_r, \xi_{k_1} \) rather than \( \xi_1, \xi_2 \).

Next, we move the lines of integration \( c_{\xi_r}, c_{\xi_{k_1}} \) to \( c_{\xi_r} = c_{\xi_{k_1}} = -\epsilon_r K \). In doing so we pass through a double pole at \( \xi_r = 0 \) and, if \( r = 1 \), through the simple poles of the \( \zeta \) factors on the second line at \( \xi_1 = -\frac{2}{3}\xi_2 \) and \( \xi_2 = -\xi_3 \). Thus, as in the previous sections, if \( \epsilon = (1, -1, -1) \) and \( (r, k_1, k_2) = (1, 2, 3) \). The contribution of the pole at \( \xi_1 = -\frac{2}{3}\xi_2 \) is

\[
\frac{1}{3} \frac{1}{(2\pi i)^7} \int_{\cdot} B^{1-\frac{2}{3}\xi_2} \zeta(1 + \frac{2}{3}\xi_2)\zeta(1 - 4\xi_2)\zeta(1 - 8\xi_2)\zeta(1 - 2\xi_2)Q_{(1,-1,-1)}(\alpha, \xi)\left(\prod_{i,j} F_{1/\delta}(s_{ij})\right) d(\cdot),
\]

and this is \( BP_{(1,-1,-1),2,3}(\log B) + O(B^{1+\epsilon\delta^{1-C_{33}} + B^{1-K}\delta^{-C_{33}}} \) with \( P_{(1,-1,-1),2,3} \) a polynomial of degree 4 and leading coefficient

\[
\frac{1}{2^{4/3}}\mathcal{J},
\]

with the notation \( \text{(7.10)} \).

The contribution of the pole at \( \xi_1 = -\xi_2 \) is

\[
\frac{1}{2} \frac{1}{(2\pi i)^7} \int_{\cdot} B^{1-\xi_2} \zeta(1 + \xi_2)\zeta(1 - 2\xi_2)\zeta(1 - 3\xi_2)\zeta(1 - \xi_2)Q_{(1,-1,-1)}(\alpha, \xi)\left(\prod_{i,j} F_{1/\delta}(s_{ij})\right) d(\cdot).
\]

and this is \( BP_{(1,-1,-1),2,4}(\log B) + O(B^{1+\epsilon\delta^{1-C_{34}} + B^{1-K}\delta^{-C_{34}}} \) with \( P_{(1,-1,-1),2,4} \) of degree 4 with leading coefficient

\[
-\frac{1}{2^{4/3}}\mathcal{J}.
\]

Thus, summarizing for all \( \epsilon \in \{1, -1\}^3 \) we have

\[
M_{\epsilon,2^\pm(B)} = BP_{\epsilon,2}(\log B) + O(B^{1+\epsilon\delta^{1-C_{35}} + B^{1-K}\delta^{-C_{35}}})
\]

where \( P_{\epsilon,2} \) is a polynomial of degree 1 unless \( \epsilon = (1, -1, -1) \) in which case \( P_{\epsilon,2} \) is of degree 4 with leading coefficient

\[
-\frac{1}{2^{4/3}}\mathcal{J}.
\]

7.7. Regrouping the various contributions. By \( \text{(7.10)} \) and \( \text{(7.11)} \), \( \text{(7.12)} \) and regrouping the contributions from Sections 7.4, 7.5 and 7.6 we find

\[
N_{\delta}^\pm(B) = B \sum_{\epsilon \in \{1,-1\}^3} (P_{\epsilon,1}(\log B) + P_{\epsilon,2}(\log B)) + BP_0 + O(B^{1+\epsilon\delta^{1-C_{37}} + B^{1-K}\delta^{-C_{38}}})
\]

\[
= BP_1(\log B) + O(B^{1+\epsilon\delta^{1-C_{37}} + B^{1-K}\delta^{-C_{38}}})
\]
where $P_1$ is a polynomial of degree 4 with leading coefficient
\[
\left(\frac{1}{16} - \frac{7}{72} - \frac{1}{48} + \sum_{\nu \neq (-1,-1),(1,-1)} \left( \frac{c_1 \epsilon_2 \epsilon_3}{2 \cdot (4 - \epsilon_1 + \epsilon_2)} - \frac{c_1 \epsilon_2 \epsilon_3}{2 \cdot 3 \cdot (4 - \epsilon_1 + 2 \epsilon_2 - \epsilon_3)} \right) \right) \mathcal{J} = \frac{1}{48} \mathcal{J}.
\]
The estimate (7.3) and then the Theorem 1 then follows by the final next lemma.

**Lemma 8.** With the notations of Theorem 1 and (7.16), we have $\mathcal{J} = \frac{1}{2} I \mathcal{G}_1$.

**Proof.** First, we observe that for $s^* = 1$ we have
\[
\mathcal{Q}_e(\alpha, 0) = \sum_{h, \epsilon, f \in \mathbb{N}^3, h \epsilon \in \mathbb{Z}} \mu(h) \prod_{k=1}^{3} \mu(b_k) \mu(c_k) \mu(f_k) \mu(g_k) \frac{(r_1, \ell)(r_2, \ell)(r_3, \ell)}{\ell^3} \varphi(\ell) \cdot 2 \pi^{\frac{3}{2}} \prod_{i=1}^{3} \Gamma(\frac{1-\alpha_i}{2}) \Gamma(\frac{\alpha_i}{2})
\]
where in the second row we computed the Euler product thanks to the lemma 2.7 of [5]. Therefore, we have
\[
\mathcal{J} = \frac{\mathcal{G}_1}{4! (2 \pi)^2} \int_{(c_{s_4}, c_{s_5})} 2 \pi^{\frac{3}{2}} \prod_{i=1}^{3} \Gamma(\frac{1-\alpha_i}{2}) \prod_{j=1}^{2} \Gamma(\frac{\alpha_j}{2}) \left( \int_{(c_{s_2}, c_{s_3}, c_{s_4}, c_{s_5})} ds_1 ds_2 ds_3 ds_4 ds_5 \frac{L(\alpha, s_{12}, s_{21}, s_{31}, s_{32})}{s_{12} s_{21} s_{31} s_{32}} \right) \cdot I \mathcal{G}_2 \mathcal{G}_3 \alpha_1 \alpha_2,
\]
where the lines of integrations can be taken at $c_{s_4} = \frac{1}{3}, c_{s_5} = c_{s_2} = \frac{2}{3}$ and, by (7.6),
\[
L(\alpha, s_{12}, s_{21}, s_{31}, s_{32}) = (1 - \alpha_1 - s_{21} - s_{31})(1 - \alpha_2 - s_{12} - s_{32})(1 - \frac{3}{2} \alpha_1 - s_{12} - s_{21} + s_{31})(-1 + \frac{3}{2} \alpha_1 - s_{12} - s_{21} + s_{31})
\]
\[
\times (-1 + \frac{3}{2} \alpha_2 + s_{12} - s_{21} + s_{32})(1 - \frac{1}{2} \alpha_1 - \frac{1}{2} \alpha_2 - s_{31} - s_{32}) s_{12} s_{21} s_{31} s_{32}.
\]
In the same way as in the end of the proof of Proposition 1, one has that the inner integral over $s_{12}, s_{21}, s_{31}, s_{32}$ can be evaluated by moving each line of integration to $-\infty$ and collecting the residues of the poles encountered in the process. After this simple but a bit lengthy calculation, which can be easily performed with the help of Mathematica, one finds that the inner integral is equal to $8(\alpha_1 \alpha_2 \alpha_3 (1 - \alpha_1)(1 - \alpha_2)(1 - \alpha_3))^{-1}$, with $\alpha_3 = 2 - \alpha_1 - \alpha_2$. Thus, we finally get
\[
(7.17) \quad \mathcal{J} = \frac{\mathcal{G}_1}{3 (2 \pi)^2} \int_{(c_{s_1}, c_{s_2})} 2 \pi^{\frac{3}{2}} \prod_{i=1}^{3} \Gamma(\frac{1-\alpha_i}{2}) \alpha_i (1 - \alpha_i) \Gamma(\frac{\alpha_i}{2}) \alpha_1 \alpha_2 = \frac{1}{3} \mathcal{G}_1 \cdot I
\]
by Lemma 4. \qed

**Acknowledgments.**—The authors are grateful to Régis de la Bretèche for helpful conversations and comments, for his supervision of the second author during the end of his PhD and for inviting the first author to Paris, where this collaboration started. The authors would also like to thank the anonymous referee for a careful reading of this paper.

The first author is member of the INdAM group GNAMPA and is partially supported by PRIN “Number Theory and Arithmetical Geometry”.
